Accident data, Raritan Copper Works 452
Accidents, influence of conditions on 767
Acme mill 317
Acupan Mining Co 882
Adirondack gold deposits again 55
Administrative continuity 712
Advancement of mining in Colorado.....G. J. Bancroft.... 910
Aeration of pulp 415
Aerial ferry 304
Agitation from a thickener.....M. D. W. Minier.... 264
Ahmeek Mining Co. report 769
Air-blasts 690
Air-compressor, portable 52
Air-lift pumping 767
Ajo 418
Alaska great goldfield 638
  Mine inspection law 234
  Mineral production 43
  Mineral production in 1914 37
  Mining laws 848, 938
  Ditto.....L. D. Leehey.... 977
  Railroad 233, 505, 627
Alaska Ebner 490, 532
Alaska Exploration Co 963
Alaska Gastineau 160, 885
  Mill.....L. E. Spray.... 612
Alaska Gold Belt Co 1002
Alaska Gold Mines Co 490, 533
  Bonds 156
  Report 781
Alaska Juneau 160, 531, 661, 773
Alien labor law (see Arizona).
Allen, A. M.....Firing boilers.... 185
Allen, A. W.....Milling gold ores in cyanide....302, 585
  Ditto.....Solution control in cyanidation.... 186
  Ditto.....A temporary zinc-box.... 657
Alloquez Mining Co 594
  Report 819
Alluvial mining, metallurgy of—I, II. John M. Nicol....837, 869
Alta Consolidated Mining Co 275, 667
Altai region, Siberia.....H. W. Turner....973, 985
Alternating current in electrolysis 804
Aluminum and copper 786
Amalgaline 914
Amalgamated Copper 531
Amalgamating plates 488, 766
  Plates, automatic dressing of.....E. S. Boalich.... 753
  Table, double-deck 113
Amalgamation in Hardinge mills 319
  Ditto.....F. J. Girard.... 110
  Ditto.....H. W. Hardinge....261, 610
  Ditto.....Francis O'Boyle.... 450
  Ditto.....K. C. Parrish.... 641
  Ditto.....J. W. Pinder.... 338
  Ditto.....G. R. Pringle.... 828
  Ditto.....M. W. von Bernewitz.... 111
A. I. M. E. constitution 2, 76
  Ditto.....E. B. Kirby, Sidney J. Jennings.... 31
  Election 282, 308
  New York meeting 323
American Placer Mining Co 235
American Reduction Co 704
American Smelting & Refining Co. report 601
American Telephone & Telegraph Co 671
American Zinc Co 422
American Zinc, Lead & Chemical Co 592
American Zinc, Lead & Smelting Co 156
  Report 856
Ammonia leaching process for copper...C. H. Benedict.... 615
Ammunition and copper 824
Anaconda Copper Mining Co 623, 821, 1004
  Exhibit.....E. S. Bardwell.... 654
  Flotation 282
  Growth 354
  Improvements at 334
  Opportunity for workmen 480
  Report 781
  Safety first work 42
Ancient river channel mining in California.....J. D. Hubbard.... 407
Andreafski district, Alaska.....E. E. Hurja.... 377
Anode, the 129
Anti-debris committee 129
Antimony in cyaniding 265
  Production 936
  Sales in New York 169
  Smelter, San Luis Potosi 776
Apex litigation, Jim Butler v. West End.....H. V. Winchell.... 763
  At Goldfield 976
Apparatus for cyanide tests.....H. F. Lunt.... 911
Aramayo Francke Mines, Ltd., report 242
Argall, P. H.....Cripple Creek ore treatment.... 135
Argentina, Mineral resources of Jujuy....A. W. Jenks.... 291
Arizona alien labor law 53
  Mineral production, 1914 90
Arizona Commercial Mining Co 595, 771
Arizona Copper Co 595
  New smelting plant 9
Arizona Copper Syndicate 496
Arizona Southwestern Copper Co 457
Arizona Venture Corporation 310
Armatures, testing burned-out.....L. V. Newton.... 329
Asbestos 998
Ashanti Goldfields Corporation, Ltd., costs 265
  Report 51
Assay of cyanide solutions.....O. E. Roodhouse.... 760
  Of ore containing metallics.....W. E. Cahill.... 865
  Ditto.....Richard Marsh.... 939
  Ditto.....G. E. McIntyre.... 641
Associated Northern Blocks (W. A.), Ltd., report 463
Atlanta Mines Co 630, 846
Atlin, hydraulic mining at.....A. D. Hughes.... 647
Atolia Mining Co 420
Attempts at iron making in India 97
Atwood Copper Co 959
Austin, L. S.....Smoke dilution at Midvale.... 579
Australia, exhibit, P. P. I. E 694
  Gold mining in Victoria 326
  Gold production, 1914 520
  Lead and zinc smelting in 802
  Lead production 8
  Zinc contracts 2, 39, 42
Austria, copper production 621
Auto trucks, severe test for 503
Automatic aerial tramway 128
  Dressing of amalgamating plates.....E. S. Boalich.... 753
  Ditto.....A. Del Mar.... 941
  Section-insulator 894
A. W. C. Mining Co 416

B

Ball, S. H., and M. K. Shaler.....Mining in Belgian Congo in 1914 403
Bancroft, G. J....Advancement of mining in Colorado.... 910

SALES TALK

BY THE ADVERTISING MANAGER

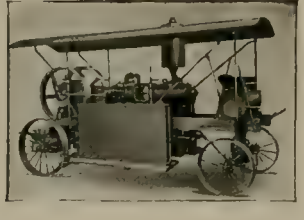
This is the first issue of the new Bulletin Service of the *Mining Press* and is devoted to the best known line of mining machinery on the market today.

The Manufacturer of the machinery described, the Ingersoll-Rand Company, was the Pioneer Builder of rock excavating equipment and its history has always been closely allied with the development of the mining industry. Its policy has always been to progress as the Industry progresses. Its designs have changed from time to time to meet changed conditions in mining.

Its various products are in such extensive use and have been so widely advertised that were you to ask the miner to enumerate, for example, the names of the various drills on the market, he would start the list with "Sergeant"—"Butterfly"—"Jackhamer"—"Leyner-Ingersoll". The same is true of any Ingersoll-Rand Product.

Undoubtedly extensive publicity could create such a situation, but it is also true that publicity alone would not maintain for the products of any manufacturer such an enviable reputation; to endure, it must be backed by value, and progress in design, material and workmanship.

Scarcely any news is published in the mining or engineering papers on the operation of specific mines and contracts, tunnel work and quarrying that does not include in the schedule of equipment some Ingersoll-Rand Products.



Only equipment possessing reliability and efficiency of the highest order could attain such recognition.

JACKHAMERS

For shaft sinking, driving small drifts, drifting benches, trimming and similar work these drills are in a class beyond compare.

The BCR 450 type has automatic rotation, mechanically operated, and may be run by air or steam. The Bull-Moose Jackhamer has automatic rotation of the hand operated type, is for air operation only and is intended for somewhat heavier work, as will be noted from the tables below. Both are rapid drillers, easy of operation and durable and will give a good account of themselves in all kinds of ground.

ESSENTIAL DETAILS

Symbol	BCR-450 type	Bull-Moose type
Length	18"	28"
Cylinder diameter	2¼"	2"
Stroke	2"	4"
Steel used	⅞" Hol. Hex.	1" Hol. Hex or larger
Weight	40 lbs.	105 lbs.
Depth of Hole Drilled	8'	12'

Bulletins Nos. 1121 and 1019

BUTTERFLY STOPER

In the mines of Lake Superior, Arizona, Colorado, and in fact all mining districts the Butterfly Stoper is bearing out our claims that over long periods of service, in raising, stoping and taking down rock it will do more work at a lower expense for upkeep than any other similar type of tool.

In a great many mines it has been adopted as standard to the exclusion of all others. An investigation will readily convince you of its superiority.

It is furnished with three styles of air feeds, and the front-head will be breached to fit any steel specified by customer.

ESSENTIAL DETAILS

Piston diameter	2"
Piston stroke	4"
Length of machine (closed)	32½"
Length of air feed	22"
Weight	72 lbs.
Size of drill steel used	1" or larger
Depth of hole drilled	6'

Bulletin No. 1211

LEYNER-INGERSOLL Water Drills

For years this drill has enjoyed an enviable reputation in mine drifting and tunnel driving, and it is today in extensive use all over the world.

It is equipped with an automatic water device for allaying the dust and cleaning the holes of cuttings while drilling, which increases the speed of drilling.

Miners everywhere are greatly reducing the cost of underground mining operations by using the Leyner-Ingersoll. It is built in two sizes.

ESSENTIAL DETAILS

Symbol	No. 18	No. 23
Diameter of Cylinder	2½"	2¾"
Length of hammer stroke	8"	10"
Length of feed	24"	30"
Diameter of hollow steel used	1¼" Rnd.	⅞" Hex.
Weight, Unmounted	150 lbs.	95 lbs.
Depth of hole drilled	8' to 12'	6' to 8'
Diameter of hole drilled	1⅝" to 2¼"	1" to 2"

Bulletin No. 1020

BUTTERFLY Rock Drill

The advent of the first Butterfly Rock Drill several years ago marked a radical departure from the prevailing reciprocating piston drill designs.

This machine has high drilling speed, is light and is very simple in construction.

In tunnel driving in the mines of the Arizona Copper Co. it helped to establish the remarkable record of 742 feet of 8x8 tunnel driven in 29½ days, 4 shifts per day, two drills in a face.

ESSENTIAL DETAILS

Symbol	C-125
Diameter of cylinder	2¾"
Length of stroke	6¾"
Length of feed	24"
Diameter of octagon steel used	⅞" and 1⅛"
Weight, unmounted	137 lbs.
Depth of hole drilled	12'
Diameter of hole drilled	1¼" to 2"

Bulletin No. 1105

INGERSOLL-RAND COMPANY

11 BROADWAY Offices the World Over NEW YORK

AIR LIFT PUMPS—STEAM PUMPS—CENTRIFUGAL PUMPS—CALYX CORE DRILLS

ELECTRIC-AIR DRILLS

For the small or isolated mine or contract where electric current is available this type of drill performs a special mission.

The electric-air drill combines with the flexibility of the electric current as power the efficiency of the compressed air drill in a complete power plant unit of great compactness and portability, solving the power plant problem and eliminating the expense of "in the mine" piping.

It is durably constructed throughout and compares favorably in drilling capacity with the standard piston drills of equal size.

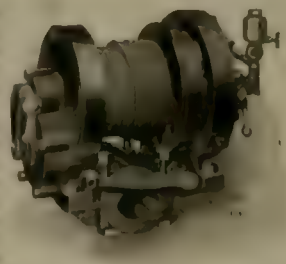
It is built in three sizes as listed below.

ESSENTIAL DETAILS

Symbol	*3-F*	*4-E*	*5-F*
Diameter of cylinder....	3⅝"	4¾"	5⅝"
Length of stroke.....	6¾"	7 "	8 "
Length of feed.....20 "		24 "	30 "
Size of octagon steel used	⅞"	1 and 1⅛"	1¼ and 1⅜"
Average horse-power required for running drill (motor output)	3	4	6

Bulletin No. 4209

"LITTLE TUGGER" HOIST



The design of this hoist is a further testament to the effort expended by this Company to excel in the product it asks the trade to buy.

It is a portable pneumatic hoist for clamping to bar, column, timber or other convenient means and is used for hoisting and lowering machines, tools and timbers in the mine, as well as hauling cars in drifts and winzes.

It has every element of safety, endurance and convenience and a comparison of the data listed below will bear testimony to its superiority for the work mentioned above.

It can be furnished for operation by steam if desired.

ESSENTIAL DETAILS

Capacity 1000 pounds at a rope speed of 85 feet per minute at 80 pounds pressure.
Clamp will fit 4½" O. D. column or arm.

Air connection	¾"
Width overall	21¼"
Length overall	16½"
Height overall	20¼"
Weight without rope	285 lbs.
Rope capacity .....500-800 ft.	

Bulletin No. 4033

LEYNER DRILL SHARPENERS

The Leyner Sharpener is an economical necessity in mining operations. It sharpens and makes all kinds of bits, true to gauge and form; and does the work more rapidly and cheaply than can be done by hand. It also shanks the steel.

Properly sharpened steel facilitates more rapid drilling and relieves the drilling machines of unnecessary wear and tear.

The Leyner Sharpener has no competition. It is built in the two sizes listed below.

ESSENTIAL DETAILS

Symbol	*No. 1*	*No 3*
Dimension in inches:		
Height	32	37
Length	52	52
Width	43	54
Weight bare, lbs.	1725	2150
Air consumption, approximate ...	75	100
Diam. bit sharpened, maximum	2¼"	3¼"
Capacity resharpening medium size steel.....50 to 100 per hr.		
Forming new bits .....20 to 75 per hr.		

Bulletin No. 4022

LEYNER OIL FURNACE

This furnace for heating and tempering drill steel is a fit companion for the Leyner Sharpener. Steels are heated quickly, uniformly, and cleanly. It burns crude oil, effecting a big saving in fuel cost in the blacksmith shop.

The capacity of the furnace is only limited by the sharpening facilities.

It is extensively used in conjunction with the Leyner Sharpener, forming one of the biggest money saving combinations that the market affords.

ESSENTIAL DETAILS

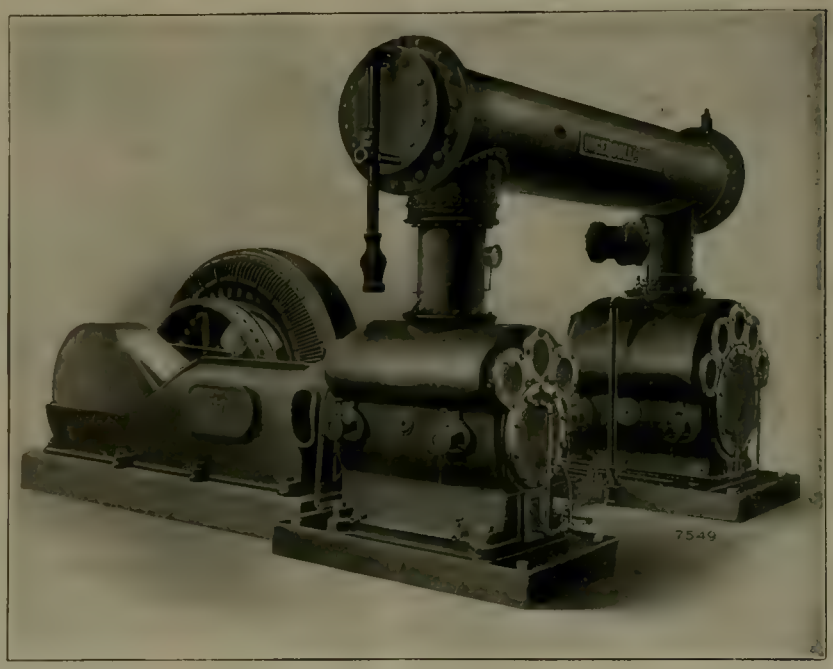
Heating surface....	7½"x10"
Heating capacity, drills per hour..	150 to 200
Air consumption per minute (free air at sea-level)	.50 to 75 cu. ft.
Oil consumption per hour	2 to 4 gals.
Floor space required for furnace only	3x4 ft.
Weight, complete..	500 lbs.

Bulletin No. 9020

INGERSOLL-RAND COMPANY

11 BROADWAY **Offices the World Over** **NEW YORK**

PNEUMATIC TOOLS—DEEP HOLE DRILL WAGONS—CHANNELERS—COAL CUTTERS



INGERSOLL-RAND COMPRESSORS

No manufacturer can point with more justifiable pride than this Company, to the performance of his air compressors. There are thousands of them in daily use in mining service, engineering work and industrial plants.

The line includes two distinctive types, the "Ingersoll-Rogler" and "Imperial," built straight line, duplex, turbo and vertical, with the following styles of drive: belt, short belt electric, direct connected electric, geared, oil engine, gasoline engine, plain steam and Corliss engine.

Sizes range between 3 and 55,000 cubic feet, pressures up to 2500 pounds.

Some of the recent "Ingersoll-Rogler" installations include the following:

Inspiration Cons. Copper Company.
Anaconda Copper Comany.
Hardaway Contracting Company.
Maryland Steel Company.

The "Imperial" compressor is the type which recently won over all other entries in an exhaustive contest conducted by the Engineers of the City of Chicago, as a result of which we were awarded the entire order for 12 machines, to furnish power for driving the water Intake Tunnels extending out into Lake Michigan.

Any of the following bulletins sent upon request.

GENERAL COMPRESSOR BULLETINS	No.
Ingersoll-Rand Compressors	3101
Ingersoll-Rogler Air Valves	3024
STRAIGHT LINE TYPES	
Ingersoll-Rogler Class ER Belt or Short Belt Driven	3030
Class NE-2 and NE2-S Belt or Short Belt Driven, for High pressures	3004
Ingersoll-Rogler Class FR Steam Driven	3209
Class NF-2 and NF2-S Steam Driven, for high pressures	3005
Ingersoll-Rogler OER Oil Engine Driven	3028
Class AA-2 Steam Driven	3003
DUPLEX TYPES	
Imperial Type XB Duplex Power or Short Belt Driven	3312
Imperial Type X Duplex Steam Driven	3311

Some New Features

OUR 110th volume begins with this number. The series is long and the career of the **PRESS** has, we believe, been both honorable and useful to the mining profession. At the beginning of this new volume several changes have been made in the form and appearance of the **PRESS**. The most striking, probably, is the shortening of the name, one of the steps in modernizing the format of a journal already up to the minute in spirit. Other changes equally important are to be made.

OPPOSITE this will be found the first **Mining Press Bulletin**, a new feature in advertising. The **Bulletin** is intended to be a condensed, up-to-date catalog of the principal lines manufactured by the firm using it. Only a limited number will be sold, but collectively the **Bulletins** will constitute a combined condensed catalog of the principal manufacturers of mining and metallurgical equipment. The **Bulletins** are printed on separate sheets and so bound as to be easily detached and placed in a separate loose-leaf note book cover of appropriate size, which will be furnished at moderate price. Engineers are urged to preserve each **Bulletin**, as the series will furnish the best guide to the most essential type of machinery and equipment. It is appropriate that the first **Bulletin** is used by the Ingersoll-Rand Company, which has pioneered in so many directions, and whose drills and compressors are known in all great mining districts around the world.

ON our front cover will be found the first sheet of the Miners' Calendar that we shall print during the year. Each month a new sheet will be issued emphasizing the dates in the month that are of especial interest to mining men, and illustrating by paragraph and picture some of the world-wide phases of metal mining. Our covers for the first of each month have been reserved for this purpose, and those for certain other dates will be used in another way to improve the appearance and increase the usefulness of the paper.

OTHER changes are pending and will be made as opportunity opens the way. The purpose of them all is to increase the effectiveness of the **PRESS** to both reader and advertiser. We purpose to make the **PRESS** not only the most interesting and authoritative journal devoted to metal mining, but the most attractive as well.

ARTICLES

THE WAR AND THE LONDON MINING MARKET.

By T. A. Rickard 6

The European war has so completely upset the normal currents of trade that the usual review of the market is impossible. Numerous mining enterprises have been hindered by the capture or destruction of steamers carrying machinery to them. Tin and nitrate shipments have decreased. Fortunately, less than 1% of the gold output comes from the areas in conflict, though disturbance of trade, by limiting mine supplies, is reacting even on gold mining. Copper shipments from the United States have decreased. Zinc smelting faces the necessity for extensive readjustment, since fighting has been most severe in zinc-smelting regions. War killed speculation in mining shares, but made gold mines the most liquid of assets.

ARIZONA COPPER'S NEW SMELTING PLANT 9

A new smelter built by an old company to treat fine ore by means of reverberatories. A series of illustrations with brief text.

APPLICATION OF ELECTRIC MOTORS TO GOLD DREDGES.

By Girard B. Rosenblatt 12

Gold dredges see hard service, and motors designed for such dredges must be with this in view, as also the short life (roughly 10 years) of the plant. The drive of the bucket chain is the real problem of the dredge. It is recommended that motors for this service be capable of carrying rated load continuously with a rise not to exceed 40° in any part; be capable of developing a torque 25% in excess of the rated full load torque, at a speed of 75% of its synchronous speed for two hours with a rise not to exceed 55°; have a maximum and starting torque of not less than 2.5 times full load.

TUBE-MILL TONNAGE CALCULATION.

By Noel Cunningham 16

A method used at the Hollinger for determining the tonnage actually handled by tube-mills working in closed circuits. It rests on four screen tests and is easily and quickly applied.

ELECTROLYTIC ZINC—THE REED PROCESS.

By E. H. Leslie 17

Many attempts have been made to treat zinc ores electrolytically. The Reed process depends upon the Hering system. It is being applied at Palo Alto to the zinc residue from the Mammoth smelter, and a successful technical operation has been worked out. In precipitation the anode is sponge-lead and the cathode aluminum. After deposition, the sponge-lead anode with its zinc sulphate coating is placed in an acid charging cell where it becomes a cathode with a dummy lead anode. It is thus restored to its original condition for re-use.

MINERS' HEALTH AT BROKEN HILL 21

Abstract of a report made to the parliament of New South Wales.

ELECTRIC SMELTING IN 1914.

By Robert M. Keeney 22

The year saw the completion and operation of the largest electric iron-smelting furnace built up to date. Work was started on the first commercial electric zinc-smelting plant to be constructed in the United States, and the first aluminum plant since expiration of the Hall patents was well started. As the result of the European war, the one electric pig-iron plant in the United States started the manufacture of ferro-manganese. Increased attention was paid to the manufacture of other ferro-alloys, and one company has renewed the manufacture of sodium in the electric furnace for later conversion to sodium cyanide.

MASONIC MINING DISTRICT, MONO COUNTY, CALIFORNIA.

By R. P. McLaughlin 27

The Masonic district lies 16 miles north of Bodie, California. No important discoveries were made till 1902 and it was in 1907 that rich ore was found. The geology of the district is briefly discussed, and the opinion is expressed that such orebodies as are discovered will be found to be extremely irregular.

ORE TREATMENT AND COSTS AT STRATTON'S INDEPENDENCE.. 29

Summary of operations for 1911-12, 1912-13, 1913-14, with detailed costs, totaling $1.38, for 1913-14.

COSTS AT THE KALGURLI MINE AND MILL 29

Detailed costs covering production of 127,870 tons of ore averaging $9.60 per ton. Dividends amounted to $461,000 and all costs $4.69.

Patented

Dead or Sweet-Roasting Gold Ores

A uniform dead or sweet-roast of gold ores for cyaniding can be secured in Wedge Furnaces.

Furnaces are constructed to use whatever fuel may be available. You can use oil, gas, coal, coke, charcoal or wood.

On account of the detailed construction of the Wedge Roaster, designed for sweet-roasting, you can secure a more uniform calcine than has been secured in previous practice with a different style of rabbling.

Wedge Furnaces are in commercial use, dead-roasting gold ores, also in commercial use, dead-roasting iron ores, where it is necessary to practically eliminate all the sulphur contents.

Write us stating analysis of ore, concentrates, mixture or material to be roasted, characteristics and physical condition of same, number of tons to be treated per 24 hours, and results desired in the calcine.

Wedge Mechanical Furnace Company

Sink Your Shaft with Sullivan Air-Jet Sinkers,

—and economize time, labor and power

Sullivan Air-Jet Sinkers at Work in a Shaft

The advantages of these tools for sinking shafts include:

(1) **Greater Speed** than is gained with tripod drills, because **Air-Jet Sinkers** have no mounting to move, require no set up, and lose no time cranking out steel.

(2) **Less Labor** is needed, since the tool is run by one man and is light and easy to handle.

(3) **Reduction in Power,** because **Air-Jet Sinkers** use less air than tripod drills.

(4) **Less Powder** and less waste excavation. Each hole is placed and pointed exactly where it will pull the ground to the best advantage.

Sullivan Air-Jet Sinkers

are equipped with hollow steel, through which air is discharged in varying amounts as needed, to clean the hole.

¶ **A Cushion Device** reduces vibration and permits high cutting speed without excessive jar to the operator.

¶ **Repairs are Light,** because all parts are made of hardened steel, from bar stock, or are drop forgings.

Progress in Metallurgy

DORR CYANIDE MACHINERY

The Dorr Agitator

has been installed in nearly every well known mill erected this year in North America and 19 machines have replaced other types. Its reliability and great economy in power have attracted much attention. Among well known companies installing them are:

Porcupine Crown M. Co.....Ont.
Hollinger Gold M. Co.....Ont.
McIntyre-Porc. M. Co.....Ont.
Porc. Vipond M. Co.....Ont.
Tough-Oakes M. Co.....Ont.
Porc.-Miracle M. Co.....Ont.
Liberty Bell G. M. Co.....Colo.
Caylloma M. Co.....Peru
Beguet Cons. M. Co.....P. I.
Fund(icion) de los Arcos....Mex.
Cam & Motor Co.....Rhodesia
Frontina-Bolivia Co.....Bolivia
Tomboy Mines Co.....Colo.

The Dorr Tray Thickener

furnishes a simple means of obtaining great settling space with small ground area, and of increasing the capacity of Dorr Thickeners already in operation. During 1914 they have been installed by

Homestake Mining Co....So. Dak.
Anaconda Copper M. Co....Mont.
Hercules Mining Co.....Idaho
Tomboy Mines Co.....Colo.
Liberty Bell M. Co.....Colo.
Aurora Cons. M. Co.....Nev.
Tonopah-Belmont M. Co.....Nev.

Flotation

Dorr Continuous Thickeners are in use in a large number of flotation plants all over the world, giving a feed of constant density and serving in some cases to recover the warm oil-bearing water from the tailings for re-use.

They have proved essential in thickening flotation concentrates ahead of filtration.

Among plants using them for this purpose are:

Butte & Superior C. Co.....Mont.
Timber-Butte M. Co.....Mont.
National Copper Co.....Mont.
Mountain Copper Co.....Cal.
Spassky Copper Co.....Russia
Braden Copper Co.....Chile
Broken Hill South Co....Australia
Broken Hill Prop., Ltd..Australia
Sulphide Corporation ...Australia
Great Cobar M. Co.....Australia
Wallaroo & Moonta Co..Australia
Amalgamated Zinc Co...Australia

Continuous Counter-Current Decantation

Owing to the success of the Porcupine-Crown plant the following companies, in the same district, have installed this method of treatment:

Hollinger-Acme, an addition of 900 tons capacity; Porcupine-Vipond, 150 tons; Porcupine-Miracle, 150 tons; Tough-Oakes, 150 tons; McIntyre-Porcupine, an addition of 150 tons.

The success of the Tonopah Mining Co. in treating silver ores by Continuous Counter-Current Decantation has induced the Tonopah-Belmont Co. to remodel their Millers plant for the same treatment.

Published figures from the Gold Roads Mines Co. show a net profit of 60 cents per ton made by changing from filtration to Continuous Counter-Current Decantation.

The Limit

in size of Dorr Thickeners was raised in 1914 from 50′ to 130′ in diameter.

Just think of one unit handling 1300 tons of solids and recovering three million gallons of clear water per day.

The construction of large units in the open air with steel or concrete walls and dirt bottoms secures great economy.

Send for our Catalogue and full data regarding the above, and also the Dorr Classifier

EMPIRE

The Name That Stands for Success in Placer Prospecting and Mining Equipment

"EMPIRE" PROSPECTING DRILL

If you have any placer prospecting to do, there are at least nine reasons why you should use the "Empire" Drill

It is the *one* accurate method of prospecting. You will have no trouble in raising capital on favorable "Empire" results.

It is the cheapest method. "Empire" drilling usually costs less than one-fourth or one-fifth as much as steam drilling.

It is the most rapid method. You can usually put down two or three "Empire" holes while you would be putting one with a steam drill. As your time is valuable this important to you.

Low freight and transportation charges, because of small total weight.

Low maintenance cost. No breakage and consequent loss of time.

No prime mover or power required other than men; therefore no fuel needed.

No skilled labor required. Negroes, Chinese, Indians, Philippinos, etc., are used with best results.

Portability. It can be taken anywhere that a man can go.

AND LAST BUT NOT LEAST—

Lowest first cost — less than half that of a steam drill.

You will find our "Empire" book a treatise on Placer Mining and it is yours for the asking; therefore write for it today.

"EMPIRE" GOLD DREDGES

In the Philippines, the "Empire" Dredge "Governor Gilbert" last month handled 82,000 cubic yards of gravel and recovered $36,500.

We secure these results with our "Empire" Dredges because we are primarily placer mining equipment engineers. We specialize in this business. We design and build each dredge to suit the particular conditions under which it is to work. And as a result it secures the highest returns and gives the best service under your existing conditions.

We place EFFICIENCY above everything else — that is, the handling of the largest amount of gravel, with the highest recovery, at the lowest possible cost.

Our book on "Gold Dredging" will interest you, and it will help you in financing your dredging proposition. Why not write for it now?

"EMPIRE" PLACER EQUIPMENT

The "Empire" line of Placer Mining Machinery includes Manganese Steel Lined Gravel Elevators, Pipe Lines, Giants, Steel Sluices and Special Riffles, Gold or Tin Saving Tables, Mechanical Tailing Elevators, etc.--- everything for the placer mine, designed by specialists who build only placer mining equipment for success.

NEW YORK ENGINEERING CO.,

The Placer Mining Equipment Specialists

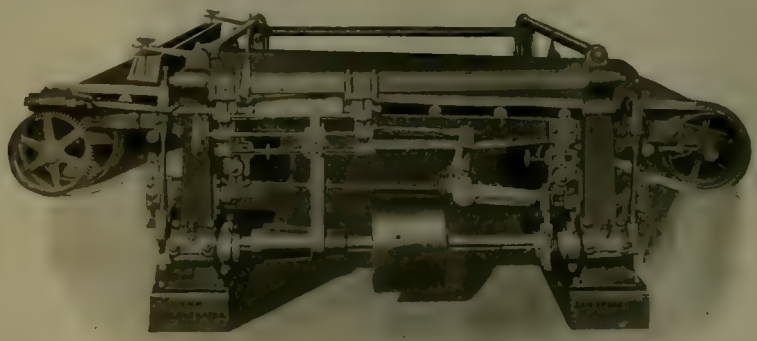
NEW YORK

Start the New Year Right

By resolving to discard antiquated milling machinery; keep in the vanguard of progress, and make a record in profits during the ensuing year.

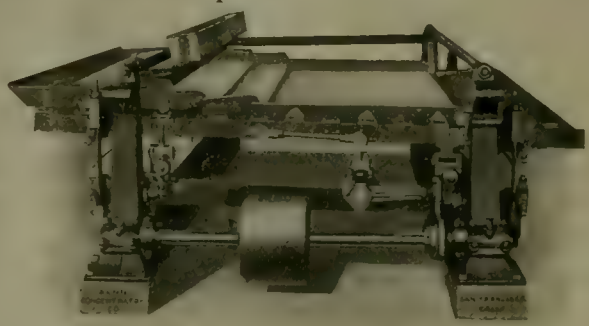
Mr. Operator, you can only do this by equipping your property with the best machinery that modern metallurgy affords. That is Pan Motion Machines.



As the last word in concentration, Senn Pan Motion Machines afford the mine operator an opportunity to begin the year with a capacity and saving in his mill which was heretofore impossible.

Operators are awakening to the fact that Pan Motion Machines have set a new standard in concentration efficiency. It is not an experiment; it is a fact that has been and is being demonstrated that Senn Pan Motion Concentrators will handle from 40 to 150 tons in 24 hours, taking unclassified feed and using but one-third of the amount of water of other machines. The Amalgamator gives a working length of plates of 500 feet and will handle from 50 to 75 tons in 24 hours, using but three-quarters of one horsepower.

This means that the initial cost of the 1915 mill will be materially under the 1914 mill, because it will be simpler, will occupy less floor space, will handle a vast amount more ore, will effect a greater saving, and establish a new efficiency record by means of Pan Motion Machines.



Keep pace with the times and write for details to the

SENN CONCENTRATOR COMPANY

500 H.P. G-E Motor Driving Underground Hoist Nourse Mines In use 6 years. No delays.

300 H.P. G-E Motor Driving Underground Hoist, Silver King Coalition Mines Co., Park City, Utah.

700 H.P. G-E Motor Driving Hoist, Crow's Nest Mines, Keystone Coal & Coke Co. 2½ years in use, 65% overloaded No delays

300 H.P. G-E Motor Driving Hoist, Iron Blossom Mining Co., Eureka, Utah In successful use over 2 years.

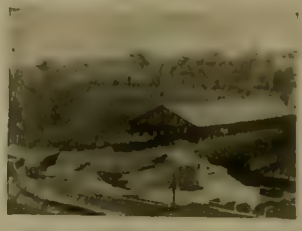
Hoists in Use Years

No Delays No Repairs

Many reports are coming in from hoists driven by G-E motors. One was designed for 24 trips per day, but has hoisted 40 for 2½ years without delay. Another has been in use six years, while others still have been in use two years or more, and in every case the report was the same: "Operation satisfactory; no delays due to electrical causes."

Mine hoists driven by G-E motors have low operating costs because, first, there are no boilers to be fired night and day; second, the absence of vibration on rope—increasing its life and that of the head gear, etc.; and, finally, because the power consumption is nothing during idle moments, but always available when needed.

Send for new hoist bulletin, "Mine Hoist Equipment."



Tipple and Track Arrangement, Crow's Nest Mine; 75,000 tons per month. In use 2½ years.

Electrically operated Tipple and Washer with Belt Conveyor, J. K. Dering Mine, Clinton, Ind.

Mine Fan Driven by G-E Multi-speed Motor, J. K. Dering Mine, Clinton, Ind.

Greensburg Coal Co.'s Tipple and Hoist House. Note absence of steam escaping.

300 H.P. G-E Motor Driving Hoist, Greensburg Coal Co. Shaft, Greensburg, Pa. Over a year in successful operation.

If You Were Asked

to draw up a set of correct legal conclusions from a miscellaneous collection of legal facts, you wouldn't try. You'd get an able lawyer, let *him* "dig up" the facts and look to *him* for correct and intelligent conclusions.

And, in the same way, correct conclusions regarding the value of your mining properties are *not* to be derived from miscellaneous facts, drawn from miscellaneous sources. Let

LONGYEAR SERVICE

"dig up" the facts, arrange them coherently and give you the intelligent result.

Here are the details of Longyear service:

The Preliminary Geological Examination.

The Survey of the Lands Examined and the Location of Exploratory Work—Diamond Drilling, Test Pitting, Trenching.

The Drilling and Recovery of Samples—Core and Cuttings.

The Geological Study of Structures and Assay of Ores by Independent Laboratories.

The Compilation of Reports and Preparation of Maps and Models.

The Filing of Records and the Storage of Samples for Reference at any time.

The Manufacture of Diamond Drills and Supplies for Immediate Dispatch to Any Part of the World.

All these comprise the branches of a complete service which, because the experience upon which it is based is unique, can not be duplicated by any other concern.

We find the ore if it is there
But we find the facts anyway

E. J. Longyear Company,
Minneapolis

GREETING

It will be remembered that in a certain city an altar was once raised to the 'unknown God.' It is more than half suspected that this was a prehistoric Scotch attempt to play safe by 'not overlooking any bets.' With the deepest sincerity, however, at this, the beginning of a new year, the Editor would like to offer on the altar of friendship a tribute from himself and his associates to our unknown friends. Strangers by face, men we never have seen, most of them men we never shall see, yet we feel between them and us the ties of real friendship. From time to time these unknown speak to us by letter and even by gift. They save out and send to us something choice from their minds or their mines, and the *Press* becomes richer by an item or the inspiration for one, while the editorial desk becomes all cluttered up with a miscellaneous assortment of specimens and keepsakes that need only some labels and a catalogue to afford the basis for a really admirable public museum. It is the letters we like best—letters written, mayhap, on nondescript paper with pencil or balky pen, dated "in camp" and, judging by the alignment, written on a board held slantwise on the knee while the beans boil. Such a letter brings the very feeling of the outdoors to us here in the office; and it brings, too, the very innermost feeling of the men who write. Prospectors would rather handle pick than pen, and only deep feeling stirs these friends of ours to write. They like, or they dislike, what we have said; and they say so frankly—giving reasons. Their reasons are always worth attention, and I assure you, Mr. Prospector, that your letters really do receive our "most thoughtful attention." It is curious, in view of the infinite ways open to an editor to make mistakes, that many more of the letters are complimentary than the reverse. Occasionally "with great regret"—we like that phrase—an old subscriber refuses longer to tolerate a young and foolish editor who perhaps has mixed over much war news with technical articles, or who has too consistently stood "on the side of the operators." One of our friends, an old Foreman whom we have never seen but for whom we have conceived a liking as well as sincere respect, writes that, while he does not expect us to employ our time in writing articles such as appear in *The Age of Reason,* many of the changes in mining of recent years have not been for the better and "none for the betterment of those employed," and that "if you even made an effort to print truth you would find your paper more widely read and appreciated." He adds that "it is not with pleasure that I write this"—and that takes away the sting. We believe him to be honest, we strive to be honest ourselves, and yet here we differ so widely. What is the truth? The question is no easier to answer here today and about matters of common knowledge in the profession, than it has been in all times and all ages. Therefore we welcome that spirit of charity—that willingness to believe the other honest, even though he be stubbornly mistaken—and to our many unknown friends, to the great multitude of our readers who never call, who never 'phone, who never write, but who, since they continue to take the *Press* either agree with us or extend the mantle of charity over our errors and omissions, to all these we offer our hearty thanks for another year's support and our hearty good wishes for the year 1915.

To our other friends, whether they be contributors, readers, or advertisers, our thanks are no less sincere. The year that has just closed has been a trying one for all, and the immediate future offers little promise of improvement. A great war cannot be fought without the whole world suffers; and a great war is not worth fighting unless it be fought to finality. We may believe as earnestly as possible in the rightness or wrongness of either side, we may hope keenly for the success of the arms to which we give support, but let us remember against the hard days of reconstruction, that these fighting peoples are the same peoples with whom we have so long had pleasant ties of business and friendship. Centuries of civilization do not altogether disappear over night; the superficial aspects of civilization may be temporarily obscured, but fundamentally the great mass of the people in each of the countries at war are the same right thinking, careful living, and well meaning people they have been all these years we have known them. Take a lesson from our friends the Prospector and the Foreman—if we must differ, let it be in kindness rather than bitterness.

What the New Year may bring in a business way to each of us cannot be foretold, but at least it will be an interesting year in which to live. In Europe one of the world's great contests will be in progress and possibly will end. In the Americas peace and industry seem likely to dominate the scene. In California we shall celebrate the opening of the Panama canal with two expositions, and at San Francisco we shall expect

to see many of our friends. Before the year closes we hope to have shifted many an 'unknown' into the 'known' column and to have intensified if not enlarged the field of our friendships. Until that pleasant day arrives when we may give you our good wishes in person, we take this means of extending them to you.

H. Foster Bain.
For the Editors.

A CONTEMPORARY records that the smokeless coal operators of West Virginia met in Philadelphia last month. It is well known that conditions are bad in the soft coal industry, but it is disheartening to learn that even stogies are beyond the reach of the operators.

RAND gold production for the first 10 months of 1914 amounted to 6,579,044 ounces, as compared with 7,143,892 ounces in the same months of 1913. The total for 1913 was 8,430,998 ounces. For 1914 it will probably be about 6,950,000 ounces. To the first of November Indian output had amounted to £1,930,649, that of West Africa, £1,424,671, and that of Rhodesia, £2,958,827.

METALLURGISTS will note with regret the absence in this number of the *Press* of the customary review of cyanidation by Mr. Alfred James, who, in the midst of war scenes finds no heart for the task. We shall later present a summary, but may note now the further peaceful conquests of the continuous decantation process, and the inroads threatened by flotation, to which such a staunch cyanider as Mr. Charles Butters has become a zealous convert.

CANADIAN questioning as to the supplying of nickel from Sudbury mines to Germany and its allies, has been met by a frank open letter from Mr. A. Monell in which it is stated that full information regarding shipments is at all times in the possession of Dominion authorities. It is also stated, as against the rumor that the Krupps are interested in International Nickel, that no European steel-maker, no individual connected with any such concern, or anyone in European financial circles, exerts any influence in the conduct of the Company or any of its subsidiaries. As to refining in Canada, Mr. Monell points out that the location of works is determined by economic conditions and that any material change in these would react to the detriment of the Canadian nickel industry. We are glad to record this full and frank statement. A company possessing a practical monopoly of any material used by the whole world has heavy and peculiar responsibilities to face, and frankness is important in meeting the difficulties that lie in the road. We sympathize with Canadians in the natural desire that their mines should not serve to equip the enemies, for the moment, of their country; and also the wish that as much as possible their raw materials should be worked up within their own national boundaries. In time nickel refining, as well as nickel mining, will be an important Canadian industry, but for the present, economics demand that Canada and the United States share the industry.

IN our New York letter the difficulties of the Australian zinc producers who have contracts with German smelting companies are discussed. As mentioned last week, the plans for a new smelter at Swansea are temporarily, at least, set aside, and it seems probable that the alternative of a new plant in the United States will, in turn, be given up. The obvious course is to ship the concentrate to the United States for treatment in existing plants. There is an adequate excess smelting capacity, and the freight movement would be along natural lines. In view of the complicated legal situation, investment in new plant to treat the Australian ore would not be warranted.

PROPOSED INSTITUTE CHANGES

Among matters which will come before the annual meeting of the American Institute of Mining Engineers in February, none is more important than the proposed changes in the Constitution, striking out the strong inhibition that now exists against the Institute expressing any approval or disapproval of technical or scientific matters or "any proposed enterprise which is outside of the management of meetings, discussions, and publications of the Institute, and the conduct of its affairs by the Board of Directors." The proposals have been before the membership for the better part of a year, but have not been as thoroughly debated as their importance warrants. As matters now stand, and as the rule has been interpreted, the Institute is absolutely tied and can do nothing but talk. In even so innocent a matter as joining the other national technical societies in issuing a common style-sheet, it has been held that the Institute could not bind itself. Recently the matter of revision of the United States mining law has been before the Institute and its members. There is no difference of opinion as to the need of some change, though much difference as to what changes should be made.

It has been proposed that Congress should appoint a commission to codify existing laws, study the situation, and report back to Congress, which would then exercise its constitutional authority (and also probably its pleasure) as to making any change. The appointment of a committee to visit Washington and urge this matter—in substance the mere investigation of a subject of the greatest and most direct importance to mining—produced a protest from the strict constructionists. Upon opinion of counsel being taken, it was held that the Institute had in fact no authority to appoint such a committee, though, in event of the proposed commission being established, it might, without violence to its own constitution, suggest to the President the advisability of appointing a mining man or two

upon said commission. These are two specific instances among many which might be cited, arising from conditions as they are, and in which the Institute was prevented from being useful, without any possible harm to any of its members. This, we hold, is a condition that results in preventing good rather than doing good. It is proposed to remove this restriction from the constitution. To make such action effective, amendment of the articles of incorporation would be necessary, and is in mind though not embodied in the formal proposal. It should be noted distinctly that the present proposal is merely to untie the hands of the Institute. No affirmative action on any proposal, or even on any plan of procedure for obtaining such action, is suggested at this time. That is a matter for the future, and we have no doubt that a sufficiently conservative attitude will be observed by the Board of Directors and the Institute membership in event of the amendments being adopted. The present matter is the determination of the question whether the Institute wishes to maintain the old attitude of absolute refusal to participate in any form whatever in matters which require more than talk. As against this, the arguments advanced are, so far as they have come to us, founded on the belief that at some time in the future, under conditions not yet realized, the Institute, if allowed to act at all, may act unwisely. We believe Mr. E. B. Kirby is right when he says in his letter in our Discussion department that, essentially, this is a feeling that we know so much better than our successors possibly can, as to what is good for them, that we are warranted in making it impossible for them to act for fear they may sometime act unwisely. We shall print other letters on the subject and shall write of it again, but boiled down to the essentials we believe this is the question: Do we as a matter of fact know the future so much better than those who will live in the future that we may justly prevent their doing what they may then consider wise for mining?

MINING

It has been said by one of the world's great physicists, that "if you want to arrive at intelligible issues—not to say conclusions—in any discussion, begin by settling the meaning of the terms you are going to use." The word 'mining' is not only the first in the name of the periodical you are reading, but it is so much the term oftenest employed that the compositors used to keep an extra supply of the letter m in their fonts in the days before 1906, when the type of this periodical was set by hand. In order to obtain a definition of 'mining' I turn to the Standard dictionary, for which I have a kindly feeling because my worthy friend the late W. H. Pettee, professor in the University of Michigan, was responsible for the definitions of words appertaining to the subject under discussion. Mining is therein defined as "the business or work of a miner or mine prospector." On turning to the word 'miner,' I find that he is "one who mines, especially one whose occupation it is to excavate ore, coal, etc., in a mine." Next, a 'mine' is said to be "an excavation, properly underground, for digging out some useful product, as ore, metal, or coal." Finally, 'ore' is defined as "a natural substance, sometimes forming part of a rock, containing one or more metals." An excavation that is not underground is usually termed a 'quarry,' the origin of which is seen in the French synonym, *carrière*, from *carrer*, to square, it being the place where squares of slate or cubes of stone are cut. *Carrière* comes from the Old French *quarriere*, itself derived from the Latin *quadratus*. 'Mine' comes from the Low Latin *mina, minor, minatus*, all of which mean something threatening. We have this meaning clearer in *minæ*, or threats, and in 'minatory,' which suggests the forefinger raised in warning. In its Latin sense a 'mine' was an excavation for confounding the enemy. Thus the military significance is older than the industrial, for the Romans were soldiers first and exploiters afterward. Mining is also the business of the 'prospector,' the latter word signifying one that can look forward. Assuredly this is a necessary function of the miner, whose work depends upon the sane use of the constructive imagination, whereby from feeble signs on the surface he can imagine or foresee the ore that lies in the heart of the hillside. The common saying that "a miner can see no farther than the point of his pick" is saturated with untruth; if it were so, he would be a fool to spend laborious days in breaking hard rock; and, what is more, if he did, the result would be nothing. Mining to be successful requires the ability or instinct to see beyond the point of the pick, sometimes many hundred feet ahead of it, and to anticipate changes in the ore due to causes that the miner has taken painstaking care to note. Indeed, foresight—the forward mental glance—is a quality fundamental to successful mining; not only as regards the behavior of the mineral lode, but in respect of the whole series of complicated processes to be performed before the result of the miner's labor is realized in terms of money.

Turning to Agricola, as made accessible to us by the Hoover translation, we find that the venerable authority describes mining as "a calling of peculiar dignity." According to him "prosperous republics, not a few kings, and many private persons, have made fortunes through mines and their produce." We may congratulate the republics; but most of us will—I believe—consider that the kings of the olden time made money by so many cruder methods that they might have left the mines to the "private persons." While the mining profession of that early day "promoted wealth by good and honest methods," it appears that the incubators of wild-cats and the pirates of finance were not unknown even then, for Agricola describes them in terms that breathe no antique air: "They either advertise the veins with false and imaginary praises, so that they can sell the shares in the mines at one-half more than they are worth, or, on the contrary, they sometimes detract from the esti-

mate of them so that they can buy shares for a small price." The same old game today, as yesterday, and until the pick is blunted forever. Yet, he insists, mining is "a calling of peculiar dignity." The trickery and the thieving is no essential part of it, nor even the scheming and gambling that loom so large in the eyes of the stock exchanges and financial press. These agencies, useful as they are, not infrequently make the mistake of putting the cart before the horse. Even the general public, using the shares of mining companies as a means of speculation or buying them with the idea of profitable investment, is apt to overlook the fact that such operations are incidental, not fundamental. Undoubtedly the charm of a successful financial venture is a factor in furnishing the inducement for raising capital, and for distributing the risk so that it may not fall too heavily on single purses; undoubtedly mining in its world-wide aspect has gained in scope and even in stability by means of the appeal to, and support from, an international clientele; without such support the digging of the metals would be restricted to smaller operations and to fewer territories. Nevertheless the function of mining is not to create counters for a gamble; that is only an incidental feature of a venturesome business.

Mining is a basic industry; it depends not upon the gambling, but upon the honest work whereby the useful and necessary minerals are extracted from the earth in order to furnish the material structure of civilization. The sunlit Mediterranean no more exists as a frame for Monte Carlo than mining for the pastime of Wall and Throgmorton streets. Share dealing is the frill on the essential digging and delving of the mine; brokerage and promotion are bubbles on the great stream of beneficent activity originating from the exploitation of mineral deposits; mining is "a calling of peculiar dignity," not a funny game for persons of nimble wit and facile morality. It is one of the two original occupations of humanity. As life progresses, man has learned to live less on the direct product of the field; literally, he does not live by bread alone; the complex way of living we call civilization depends increasingly upon the metals. By means of them we move, communicate and construct; by the use of them we obtain heat, light, and a thousand comforts. They furnish the munitions of war no less than the implements of agriculture and the instruments of scientific research. The world may suffer a diminished supply of the metals for a while, as during a great war, but not for long. It can endure the obliteration of all its stock exchanges before it can dispense with the products of the mine. Lacking them, it reverts to a material barbarism in which the finer fruits of the human spirit decay. Under the barren overburden of ruthless militarism, as under the gentle meadows of peaceful progress, is the bedrock of metal. On that the sky-scrapers of civilization are founded. The relapse of war serves to give thundering emphasis to the fact. Mining is a basic industry.

T. A. Rickard.

SPECIAL REVIEW NUMBERS

Contrary to our custom of recent years, we do not present our readers today with an Annual Review Number. The reasons for the change lie both in the business and editorial situation. As to the first, it may be said that among technical journals the constant tendency of recent years has been away from special numbers. Formerly such extra efforts were common and advertisers were continually importuned to furnish funds for some wonderful extra edition that was to secure marvelous publicity at a minimum of cost. Frankly, results have shown that this was a poor policy for both advertisers and publishers. Money spent spasmodically in advertising is ineffectively spent. It is persistent work that counts, since the benefits of advertising are cumulative. The *Press* never went far in the field of special numbers, though it has several notable ones to its credit. From a business point of view, however, it is better for both publisher and advertiser that the work of making the best paper in the field should be steady and persistent. Instead of the best review number, it is our ambition to print the best paper each week in the 52 that make up the year. Other papers will in time follow this plan. We are merely adopting it first. From the editorial point of view the situation is similar. With a special number in prospect, the tendency to save up special articles for it is strong. There is also the necessity, in order 'to round out' the number, to fill in with padding and rehash. The most successful editor cannot obtain a notable review of each department in mining and have them all ready and all fresh, for the same week. The reason is obvious—nothing of consequence may have happened in some of the departments, and in others the man who should write the review may, for any one of a dozen reasons, be unavailable at that time. As for statistics, the significant figures in many lines are not available the first of January, some, such as iron ore shipments, Alaska gold output, and others, are already old. Many are not yet collected. Formerly certain journals made a great pretense of collecting their own figures. There was always but a small infusion of original matter, and for years all the technical journals have received, with a uniform release date, their most important figures, such as the estimates of gold and silver production made by the Bureau of the Mint, and the admirable reviews of the industry now furnished by various geological surveys and mine inspectors, from public agencies open to all. The *Press* prints this week, and will print each week, such of this material as is available and authentic. It will also print throughout the year, and as time and writer come into happy coincidence, significant reviews of technical progress in various lines and of mining development in the numerous states and countries in which its readers live. These reviews will be authoritative and up to date. As evidence of good faith we publish in this number numerous brief reviews of districts, and a careful summary of progress in electric smelting, by Mr. Robert M. Keeney.

PROGRESS IN COPPER METALLURGY

The progress of copper metallurgy is much like that of the amoeba; a thrust forward comes now at one point, now at another, but the net result is that the whole body progresses at a fairly steady rate. The conditions to be met change from month to month, and attention is directed now at one set of conditions, now at another. Today when everyone is talking of hydro-metallurgical methods, it is hard to realize that a decade ago blast-furnace smelting, now largely neglected, was a similarly absorbing topic. At that time the roasting of copper ore was nothing like the fine art it has since become, nor had reverberatory furnaces reached their present stage of development, so that the heat efficiency of a reverberatory furnace was low. Blast-furnace smelting, with the ore in intimate contact with the fuel, was so much more efficient and cheap that metallurgists were generally confident that it would continue to hold the leading place. The ore deposits then worked and the methods of mining then in vogue were such that lump ore was abundant and the view seemed justified. In the immediately preceding period blast-furnace smelting had developed a problem through mining operations (in most places) penetrating to depths below the oxidized ores, so that the sulphur and iron content of the ore mixture became too high and the copper content of the resulting matte too low for economical work. Copper metallurgists were clever enough to perceive quickly that if the sulphur and iron could be oxidized in the blast-furnace they would furnish heat, thereby doing away with the necessity for an equivalent amount of coke, which is expensive, and besides, being bulky, displaces ore in the smelting zone and so cuts down daily capacity. Many bright minds addressed themselves to the study of this problem, and it was not so long before an elaborate technology was worked out so thoroughly that, with an ore high enough in sulphur, it was found quite possible to smelt copper ore in the blast-furnace without using any coke at all.

The successful smelting of copper ore in the blast-furnace without the use of coke was a notable achievement, and yet the economic advantage was largely nullified by an extraneous circumstance which could scarcely have been foreseen. The period was one of rapidly increasing use of copper, and the geologists and mining engineers were busy in searching for new deposits of copper ores. They soon found that large deposits of material containing 25 to 50 pounds of copper per ton, in the form of disseminated sulphides, were available if any use could be made of them. Direct smelting of such ores was out of the question, but in the Lake Superior region, ore of a like content had been, for many years, cheaply concentrated. It had not been supposed that such low-grade sulphide ores could be profitably concentrated, but properly directed experiments soon showed that they could, and that with large-scale, low-cost mining and milling a good operating profit could be made on the operation. But no blast-furnace could possibly handle the resulting finely crushed sulphide concentrate, roasting and smelting in reverberatory furnaces became a physical necessity. This directed attention toward both these operations, and it was soon found possible to reduce the cost of roasting, improve the product and to increase the tonnage per roaster. Even greater progress was made with the reverberatory. Changes in the design increased its thermal efficiency and tonnage smelted, and the introduction of boilers into the flues leading away from the reverberatory made a great saving in the cost of fuel. About this time crude petroleum became abundant and cheap, through other extraneous causes, and its use as a fuel led to smoother working and cheaper costs in those regions where its comparative cost per ton, plus relative freight costs, enabled it to supersede coal. The amount of flue-dust made by a reverberatory is small, and its economy in this regard as compared to rehandling the abundant flue-dust made by a blast-furnace, coupled with the reductions in operating costs made by the improvements above mentioned, soon put reverberatory smelting almost on a par in operating cost with blast-furnace smelting, and the latter now no longer enjoys the tremendous lead it so long possessed. Blast-furnace smelting, except as an adjunct to reverberatory smelting, therefore bids fair in the future progressively to decrease.

The fine crushing to which low-grade ore must be submitted to prepare it for concentration leaves it in a state of division most suitable for the application of hydrometallurgical processes, and the tailing from such concentration may therefore be considered as material ready prepared for treatment on which all costs up to that point have already been paid. This gives to such processes an advantage not previously possessed, and a great amount of study has been directed toward devising for low-grade copper ores some wet process that in cheapness, efficiency, and completeness of recovery might be at least comparable with the cyanide process for gold. Notable progress has been made already in this endeavor, and the advance still continues. Oxidized ores, and low-grade ores which have not been subjected to concentration, will share in the benefits which such a process will bestow upon the treatment of copper ores. All the work so far goes to indicate that the leaching solution used in nearly every case will be a dilute solution of H_2SO_4, and the necessity for an abundant supply of cheap acid is likely to affect general smelting operations in such a way that the necessary sulphur may be recovered from the smelter fumes. This is fortunate for the smelter men, since of recent years they have been increasingly harassed by suits to recover for damages alleged to have been caused by the sulphur content of the escaping gases. Recent tendencies in copper metallurgy have therefore been the working of lower and lower grade deposits, the devising of large-scale mining operations to reduce the cost, a tremendous growth in milling in order to reduce smelting costs, the necessary employment of reverberatory smelting, with improved technique, and lowered costs.

The War and the London Mining Market

By T. A. RICKARD

Since August a state of war has existed in Europe and the following principal countries have been drawn into it:

Great Britain	Germany
France	Austria
Russia	Hungary
Belgium	Turkey
Serbia	
Japan	

To these must be added the overseas dominions and colonies of the countries implicated:

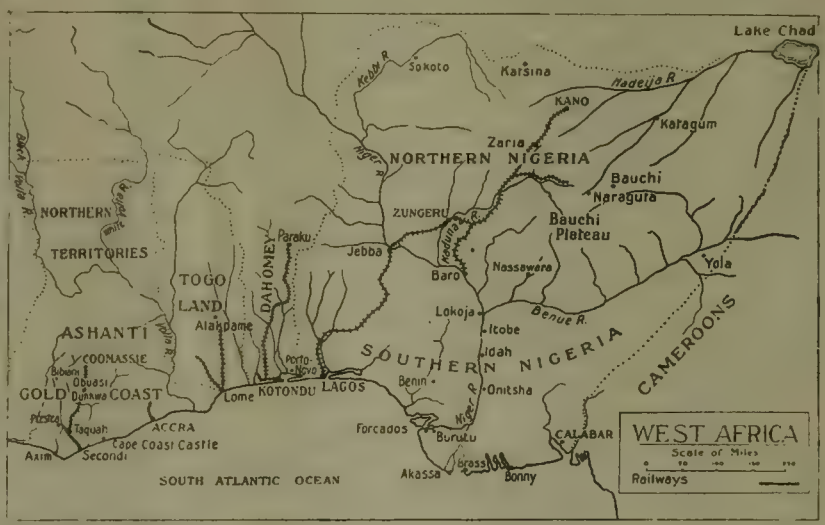
Canada	German Southwest Africa
Australia	South Africa
New Zealand	Belgian Congo
India	Cameroons
Egypt	Togoland
Samoa	Angola
West Africa	Arabia

Montenegro must be included; also Portugal, for the Germans have invaded Portuguese East Africa, while the fighting at Kaiochau brings China into the arena. Naval operations have taken place off the coasts of Iceland, South America, and East Africa, in the Persian gulf, and on the high seas generally. In short, it is apparent that the fighting and devastation have spread over the whole map. It is a world-war. Mining is a world-wide industry. Therefore the conflict has produced most serious and highly complex results.

Fortunately the mines whence come the metals necessary to modern ways of living are situated inland, and chiefly in the mountains of the interior, in distant regions, so that they are far removed from actual warfare. Europe is a consumer rather than a producer of the non-ferrous metals. The shock of war has destroyed a market rather than closed a source of a commodity essential to civilization.

Immediately after the declarations of war, in the first week of August, the entire system of ocean transport was disorganized. But that did not last long. Soon the British navy established control over the main trade routes and a resumption of maritime commerce became possible to the Allies and to neutral countries. But not without risk. Among the casualties of mining due to the war, may be mentioned the loss of pumping and hoisting machinery, together with converter parts, intended for the Ridder, Tanalyk, and Kyshtim mines in Siberia, all of which went to the bottom of the North Sea in the *Bruno*, which was sunk by a floating mine in September. The *Clan Grant*, sunk by the *Emden's* guns in the Indian ocean in October, carried machinery and supplies for the gold mines of the Kolar district, while the *Troilus*, another victim of the *Emden*, had a cargo of 925 tons of tin from the Straits Settlements. Sundry shipments of copper—beginning with that on the *Kroonland*, arrested at Gibraltar early in the war—have been stopped or delayed on their way from New York to European destinations.

The dislocation of trade along the South American coast, due to the general internment of German shipping, and the later raids of one or two German cruisers, injured the mining industry of Chile, Peru, and Bolivia. Most of the nitrate works had to be closed; at Chuquicamata delay was caused by the fact that orders for cement and machinery had been placed in Germany just before the war; in Bolivia the tin mines ceased operations until the government made arrangements to buy and to store the concentrate. Unquestionably, the



mining regions of South America have felt the war acutely.

Shipments of tin from Northern Nigeria ceased entirely during August on account of the use of the railways for the transport of French troops and military supplies from Dahomey across Nigeria to the Cameroons. In the same way, copper mining in Namaqua-land was hindered by operations against Raman's drift on the border of German Southwest Africa. On the other hand, the insurrectionary movement headed by De Wet and Beyers, in the Union of South Africa, had no immediate effect on the mining industry, especially of the Rand, because the resulting military operations took place at a distance from the mines; nor did this futile revolt

affect the supply of native labor to the Rand gold mines.

Siberian mines have escaped serious injury. The immediate effect of Russian mobilization was to withdraw about a third of the workmen, except in the Altai, where the nomadic Kirghiz are employed. In October the arrival of Austrian prisoners of war, on parole, helped the mines, for many of these prisoners were allowed to accept employment. Of course, the building of new plant had to cease, on account of the delay in shipments of machinery; development work underground also had to be curtailed; but production proceeded much as usual, because the metals find a domestic market. Gold, of course, is readily absorbed; but copper also, the Russian import-tax serving as a bounty, which makes the price of copper about £103 per ton to the Siberian producers. So far, the war has done but little direct harm to Russian mining, and we shall be surprised if the conclusion of peace does not cause fresh friendly attention to be given to operations, in Siberia more particularly.

Gold Production and the War

As regards gold, it is a fortunate fact that Europe yields less than 1% of the world's production. Of the total, 63% comes from regions under the British flag, chiefly the Transvaal and Australia, while 18% comes from the United States. None of the Russian output is derived from regions anywhere near the arena of war. To promote uninterrupted production in the British dominions, the government arranged with the Bank of England to advance 97% of the value of the gold when deposited at local banks, the remaining 3% being adjusted subsequently, after the bullion had been shipped to London, this being postponed until it could be done safely, under convoy. Thus English mining companies were able to realize upon their gold in London. The American and Siberian gold mining districts were not affected by the war, each having an ample domestic market for their precious produce. A more immediate danger was a shortage of supplies, such as cyanide, zinc, and drill-steel, as well as machinery parts. The South African mines had been obtaining fully 60% of their cyanide from Germany, the total consumption on the Rand alone in 1913 being over 10,000,000 lb. of that chemical, representing an expenditure of $2,120,000. Other gold mining districts were, wholly or partly, dependent on German manufacture. However, an adequate supply was soon assured from Scotland, as regards the major demands, while successful efforts were likewise made at New York for an increase in the domestic output, concurrently with the release, through Holland, of some of the stock accumulated in Germany. Fortunately, the disorders in Mexico had diminished the requirements of the silver mines, otherwise the scarcity in the United States and Canada would have been more pronounced. Zinc, in sheet form, for making the shaving used in the precipitation of gold, was another prime requisite. The supply, for South Africa particularly, suffered from the closing of the Belgian and German smelters, but the relatively small quantity required in cyanidation was soon forthcoming, chiefly from the United States.

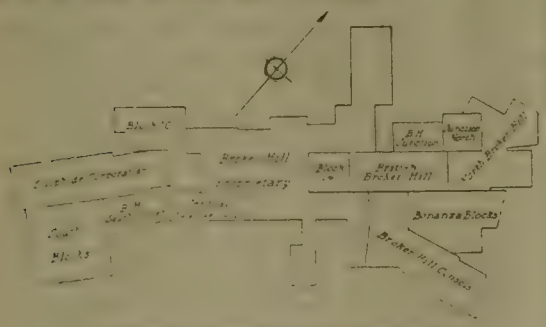
Copper has played an important part in the war, not only as a metal necessary to the manufacture of armament and munitions, but as contraband causing friction between neutrals and belligerents. Among the latter, Russia is the biggest producer of copper, her output of 45,000 tons being wholly absorbed in domestic consumption. The copper mines of Mansfeld and Rammelsberg contribute about 25,000 tons to the German consumption of 250,000 tons per annum. England consumes 140,000 tons of copper and produces none, while France uses 100,000 tons, all of which is imported. The United States yields 550,000 tons, or slightly more than half the world's total production of this metal, and consumes 340,000 tons; so that an export of 210,000 tons is required to maintain the normal level of output. Owing to the loss of the German market, besides the general slackening of world-wide industry, involving a lessened consumption of copper, by no means compensated by the use of it in war apparatus, the copper mining industry of America has suffered severely. For a while Holland served as a side door into Germany, the shipments to Rotterdam in September amounting to 5500 tons of copper, as against a normal annual consumption in Holland of 1000 tons only. The subsequent closing of the North Sea, owing to the presence of mines, has closed this market. As the war proceeds the embargo on contraband is becoming more effective, and more irritating to neutral countries desiring to continue business with belligerents. This, however, was anticipated in America as early as August, at which time the larger copper mines reduced their operations to half-capacity, while many of the smaller mines ceased production entirely. At the same time the decline in the price of the metal from 13¼c. in July to 11¼c. in October, tended further to restrict output. This result is due mainly to the closing of the German ports, that country consuming one-quarter of the world's entire copper production. Meanwhile, the corresponding drop in the London price of copper, from £65 in June to £51 in October, has compelled most of the Australian copper mines to curtail production or to cease operations entirely. The Mount Morgan, Wallaroo & Moonta, and Mount Lyell are working on half-scale. The Hampden-Cloncurry and other mines in Queensland have had to shut down owing to a suspension of selling contracts. Indeed the dependence of the Australian copper industry on the German market is strikingly emphasized.

Zinc Mining and Smelting Upset

As regards lead and zinc, the invasion of Belgium and the belligerency of Germany have stopped the smelting of the Broken Hill concentrates that formerly went to Belgium, Rhenish Prussia, and Silesia. This means the temporary cessation of an important industry in Europe and the crippling of an equally important industry in Australia. The mines at Broken Hill in 1913 yielded 525,000 tons of concentrate containing 45%

zinc and 5% lead, representing therefore 236,250 tons of metallic zinc and 26,250 tons of lead. This output was accompanied, as a part of the ore-dressing operations, by the production of 350,000 tons of lead concentrate, carrying 65% lead and 6% zinc, containing therefore 227,500 tons of lead, with 21,000 tons of non-recoverable zinc.

Naturally mining operations at Broken Hill were disorganized as soon as the war severed communication with the European smelters to which this big production had been consigned. Of the total output of zinc concentrate only 21,000 tons was being treated elsewhere, namely 12,000 tons by the Broken Hill Proprietary Company at Port Pirie, in South Australia, and 9000 tons by the Central Zinc Company at Seaton Carew, in England. Of the lead concentrate, the Port Pirie smelter was receiving 170,000 tons, while 30,000 tons was consigned to the Sulphide Corporation's smelter at Cockle Creek, in New South Wales. Thus 500,000 tons of 45% zinc concentrate and 150,000 tons of 65% lead concentrate were being treated in Europe, and of this grand total only 9000 tons of zinc concentrate was diverted from Belgium and Germany.



PRINCIPAL PROPERTIES AT BROKEN HILL.

During September an arrangement was made whereby the Port Pirie smelter undertook to treat only one-half the Broken Hill Proprietary's output and was thereby enabled to accept the production of the North, South, and Zinc Corporation mines, each of which, as well as the Proprietary, is working on half-time. The British Broken Hill is shut down. The Cockle Creek smelter has been unable to accept any tonnage except the output of its affiliated mine, namely, the Central, belonging to the Sulphide Corporation.

The enforced idleness of the German and Belgian smelters also affected the Bawdwin mine of the Burma Corporation, which had just begun to ship its complex zinc-lead ore to Rotterdam, for the German smelters. It also affected the Sardinian, Algerian, and Spanish zinc ore and concentrate that formerly went to Belgium; and the Bolivian tin concentrate, a large part of which used to go to Essen and Hamburg, both in Germany.

Sundry schemes for the erection of a zinc smelter in England, together with serious talk of building a large lead plant, have not come to fruition, largely on account of adverse monetary conditions, but several groups of experienced financiers have the matter under consideration. It remains to be seen whether the war will last long enough to effect a permanent transfer of industry. As Great Britain consumes exactly the amount of zinc that is contained in the concentrate shipped from Broken Hill, it would seem advantageous to extract that zinc at a domestic smelter, seeing that the fuel, clay, and labor are available. Indeed, the further erection of a lead smelter adjacent to a zinc plant commends itself on economic and political grounds.

One immediate result of the war is to lay bare the fact that the German metal companies and their associated smelters have obtained a big control of the metal trade in London. Most of the Australian lead and copper companies have been tied to them, while the price of zinc has been manipulated by the cartel to such an extent as to constitute a scandal. Indeed, the English mine operators are becoming aware now to what a surprising degree the German metal merchants and brokers, together with their New York allies, have gained a hold on the big business of buying and selling the metals. Obviously any glaring abuse of this control can be rectified by insistence, on the part of the mining companies, upon the inclusion of a clause in their contract specifying that the final adjustment of payment shall be made on the price at which the metal recovered, from the ore or concentrate, is actually sold. At present both the miner and the consumer are the easy victims of the broker who speculates on the rise and fall of metals with an unfair knowledge of the conditions affecting the market.

Speculation Killed by War

War has killed speculation in mining shares, and it has put a quietus on the promotion of new enterprises. The pun that floating mines in the North Sea engage more attention than the floating of mines in the City is inevitable, because it conveys a fundamental fact. The great industry of mining, however, proceeds in every quarter of the globe, except where the warring hosts are assembled. A productive gold mine is today the most liquid of assets. The metals are still wanted, and will be wanted in increased quantity as soon as hostilities cease. Material civilization is built with them. When this abnormality of organized murder is ended, the peoples of the earth will return with intensified ardor to the expansion of those peaceful industries that depend so largely upon the produce of the mine.

Gold recovered from 873,635 cu. yd. of gravel at the Lena, Siberia, from October 1, 1913, to September 30, 1914, totaled 370,256 oz., worth £1,391,532. A further £108,618 was saved from slag and outside purchases, making a total value of £1,500,150 ($7,200,000).

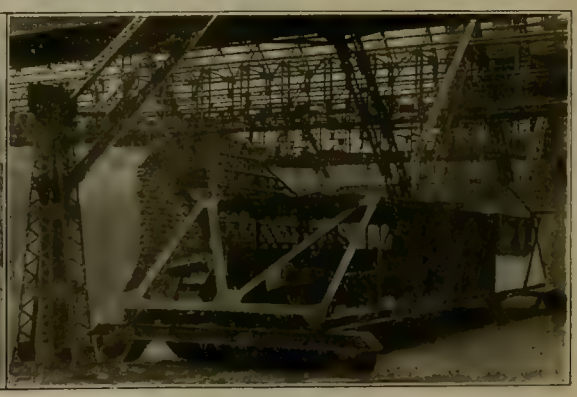
Gold output of British Guiana, South America, for the current year to November 5, was $937,636, compared with $1,167,246 in that period of 1913. The diamond yield was 9517 and 5941 carats, respectively.

Arizona Copper's New Smelting Plant

The Arizona Copper Co., Ltd., one of the old and well established copper companies of the Southwest, completed and put into operation last year a smelting plant that is in many particulars a model of the best modern practice. Through the courtesy of Norman Carmichael, general manager, we present a number of views of the plant. The total cost was $2,100,000. A detailed statement of construction costs was prepared by E. Horton Jones, the constructing engineer. An abstract, with flow-sheet of the works, was printed in the *Press*, August 8. L. D. Ricketts, as consulting engineer, was responsible for the design, and Repath & McGregor drew the plans. While ample space has been left for blast-furnaces, smelting is for the present conducted entirely in oil-fired reverberatories. Steel and concrete have been used liberally in construction.

There are three reverberatory furnaces, eight Herreshoff roasters, and three stands of converters. The whole plant is designed so as to have ample capacity in reserve and so insure continuity of operation. It is served by the Arizona & New Mexico railroad, and within the works there are 1½ miles of electric trolley road and about four miles of standard-gage steam road. The plant is on the San Francisco river about two miles below Clifton. The Company owns eight producing mines at Morenci, Metcalf, Longfellow, Garfield, and Coronado. Over 90 per cent of the ore treated comes from the concentrators. Such coarse ore as comes from the mines is crushed and sampled before treatment. In addition to the smelter the Company operates a leaching plant for treatment of oxidized ores and has been the pioneer in much good work.

STOCK PILES AND SAMPLING WORKS.



MESSITER RECLAIMING MACHINE.

AIR-COMPRESSORS AND TURBINES.

BOILER MACHINE SHOPS.

Power from waste-heat boilers is supplied for the smelter and for transmission to the mines. The boilers are Stirling class M No. 26 water-tube. Curtis turbines furnish current at 13,200 volts, for transmission to the mine and the current taken at 440 volts for general use and 110 for lighting around the works. Connersville rotary pumps circulate water for the turbines. Nordberg blowing engines furnish air to the converters. They are cross-compound, duplex, steam cylinders being 22 by 42 in., and air cylinders 44 by 42. They are designed for steam at 160-lb. pressure and 75° superheat and each engine compresses 10,000 cu. ft. to 12 lb., at 71 r.p.m. Guaranteed steam consumption is 1.1 lb. per 100 cu. ft. of air.

ROASTERS' CALCINE DISCHARGE.

After sampling, the ore goes to bedding piles from which it is reclaimed as needed and sent to the roasting department, over a Merrick weightometer. Herreshoff air-cooled furnaces are used. These furnaces have six roasting hearths and one for drying. They are of 21½ ft. diameter, 18 ft. high, and each requires 3 hp. and 2400 cu. ft. of air per minute at 1¾ oz. pressure. The air is furnished by Buffalo fans driven by General Electric motors. The capacity of the roasters is 70 to 100 tons per day. The dust goes to a 48 by 180-ft. chamber with double hopper bottom and 1325 sq. ft. cross-section. In it pieces of No. 10 steel wire and ⅜-in. chains are suspended, the wire on 4-in. centres.

FLUE-DUST CHAMBER AND ROASTERS.

DISCHARGING SLAG.

CASTING MACHINE.

CONVERTERS.

There are three 22 by 100 ft. reverberatories, of which one is held in reserve. They have the usual silica bottom and are fettled through holes in the roof, using silicious ore. Converter by-products as well as silicious ore are brought to the furnace in small cars running on track over each side of the furnace. Each furnace has two matte tapholes from which matte is drawn into 20-ton cast steel ladles. Slag is taken away in Treadwell slag cars hauled and tilted by electricity. Oil is fed by the Wilgus system, and tank capacity is sufficient to permit careful measurement and recording of the amount of oil used by each furnace. The reverberatories furnish heat to seven boilers of 712 hp. each.

CONVERTERS; MATTE RECEIVING END.

FIRING END REVERBERATORY FURNACE.

There are three converter stands, and four 12-ft. upright Allis-Chalmers shells. The converters are lined with magnesite bricks, and are built with 15-in. vertical distance from the bottom of the dished portion to the tuyeres. Matte is brought to the converters in 12-ton ladles, handled by means of Morgan cranes. Each crane is of 40-ton capacity and has a 15-ton auxiliary hoist. Work is expedited by storing silicious ore so it may be spouted direct into the converters. There is a separate chamber for converter dust. It is 25 by 130 ft. and is hung with steel wires and chains as in the larger chamber. Copper is cast in two straight-line casting machines.

Application of Electric Motors to Gold Dredges

By GIRARD B. ROSENBLATT

A gold dredge is a piece of machinery designed to dig gold-bearing gravel, sand, or clay, and to treat the material so dug in such a way as to recover the gold content. It, accordingly, consists essentially of two parts, one the digging part, and the other the gold-saving part.

Hard Service in Dredging

From the point of view of the application of electric power, the digging end is of particular interest, as the mechanical requirements are severe and the speed control must be exceptionally good. The gold-saving end does not differ very materially as to motor applications from those of the usual metal mining mills, except possibly that the equipment is exposed to a little more abuse and that compact methods of drive are necessitated.

Electric power has been applied very generally of late to the driving of gold dredges, owing to its convenience and economy. Of the $88,400,000 worth of gold produced last year in the United States, nearly a fifth came from dredges, and in view of the fact that gold is being recovered by means of dredges in practically all of the Western states, in most of which localities hydro-electric central-station power is available, a few remarks regarding the essential characteristics of successful motor drive may be of interest.

In designing electrical apparatus and applying it to gold dredging, the electrical engineer is often too prone to approach the problem from the point of view that the dredge should be designed particularly to permit of the most favorable application of electrical apparatus. A successful dredge is primarily designed to make money. Electric drive is merely an incident in the process, so that, while it is unquestionably often advantageous to modify the ordinary dredge design so as better to accommodate it to the characteristics of the electric drive, nevertheless the fact should not be lost sight of that the electric drive is simply an incident to effect economy, and that other considerations are often of greater importance than the most advantageous installation of a particular type of motor in a particular manner.

In considering how electric drive can help the dredge make money, the following factors enter into the total charge against the electric plant: (1) Interest on investment, which is affected by the first cost of any particular arrangement; (2) power charges, which are affected by the efficiency of the motors and the system of control; (3) maintenance charges, which are affected by the type of apparatus chosen; and (4) delay charges, which may be very seriously affected by proper or improper application.

As stated above, the gold-saving end of a dredge does not offer any particularly great problems in the application of electric drive. A motor is required to drive either a shaking or revolving screen, which removes the coarse rock from the finer gold-bearing sand and gravel. This motor may be either geared or belted to the screen. Gearing is preferable on account of its saving in space, but belt drive is preferable as far as the motor is concerned on account of the damping effect upon the vibration incident to the screening operations. Squirrel-cage motors are generally used for this purpose and are entirely successful, but some designers advocate motors with phase-wound secondaries in order to reduce the strain at starting. The writer is inclined to favor the squirrel-cage motor on account of its freedom from details which may increase the maintenance charge.

All of the gravel and sand which passes through the screen must be washed in order to obtain the gold from it, and for this purpose a considerable volume of water must be pumped. Centrifugal pumps are usually used on account of the low head and large volume to be handled, and these are best driven by direct-connected squirrel-cage motors. Apart from those features which tend to reduce the maintenance charge, such as adequate insulation, adequate air gap and adequate bearings, the efficiency of these pump motors deserves consideration as the amount of total power used by the dredge for pumping is very considerable, usually as high as 40%, and sometimes higher.

Handling the Tailing

The tailing or residue that is sorted out by the screen must be removed to some distance from the hull of the dredge so that it will not pile up under the hull and strand the dredge. Two methods of taking care of this material are in use. One, the less common, is to pass the waste down a chute, helping its progress with a stream of water. The other, and by far the more common, method is to employ a belt-conveyor running out of the back end of the dredge for a distance of 90 ft. or more, which conveyor is commonly referred to in dredge practice as a stacker. This stacker is motor driven. The service is reasonably severe, owing to the fact that the motor is usually at the far end of the stacker and therefore often exposed to the weather, and also due to the fact that when the stacker has been at rest, considerable torque is required to start it loaded. In cold climates, a stacker when at rest is often likely to freeze, due to the moisture contained in the waste being carried by it. Starting under these conditions is particularly arduous, and in some places this trouble is overcome by putting the stacker in a continuous canvas tent like a tunnel and passing steam pipes from a little low-pressure heating boiler up inside this tent.

*Abstract from *Transactions* of Am. Inst. Elec. Engineers.

This again makes life hard for the motor, because moisture vaporized by the heat of the steam pipes rises to the far end of the stacker where the motor is situated, and there often condenses on the motor whenever that machine is shut down and allowed to cool. Accordingly, a motor for stacker service should primarily be designed with adequate insulation to resist continued moisture, and in some cases drip guards have advantageously been placed over the ventilating openings in the motor. Squirrel-cage motors with heavy torque characteristics have been used successfully for stacker drive, but the general tendency is to use motors with phase-wound rotors in order to obtain a good starting torque. Here again is the question whether complications of a phase-wound motor are justifiable, and in my opinion it is probably preferable to use a squirrel-cage motor designed for good torque characteristics, with possibly a trifle more resistance in the secondary circuit than is found in standard squirrel-cage induction motors. A stacker motor is comparatively small compared with the total motor installation on the dredge, and a slight loss in efficiency on such a small unit is more than offset by a saving in maintenance.

The Digging End

The application of electric power to that portion of the mechanism used for digging, is a much greater problem than anything met with in connection with the other applications on the dredge.

Power is required at the digging end primarily for driving the bucket chain, but some power is also required for lifting and lowering the ladder and for operating the devices that pull or hold the dredge up against the bank so that the buckets will bite into their work. Ordinary winches similar to those often used on seagoing vessels are used for these purposes. The duty of the motors is entirely akin to ordinary hoisting service and of very intermittent nature. An intermittent rated wound-rotor motor with high torque characteristics is successfully used.

The drive of the bucket chain is the real problem on the dredge, and no system that has ever as yet been devised has proved itself entirely free from all objections. For one thing, power requirements are at times excessive, and vary through a wide range. Accurate speed control is also essential. Good economy is of importance on account of the comparative size of the digging motor compared with the rest of the installation (in this connection it might be stated that the digging motor is usually from 35 to 45% of the total motor capacity on the dredge). Greatest of all is the problem of adequate and successful mechanical connection between the motor itself and the bucket chain.

The power requirements for driving the bucket chain under ordinary conditions may be calculated reasonably close when the size of buckets, the number of buckets handled per minute, and the type of ground to be dug are taken into consideration. The following table gives some fairly typical test results.

Place	Size buckets, cu. ft.	Buckets per minute	Motor rating, hp	Aver. hp input
Oroville	5	18	75	65
Marysville	7	20	150	140
Marysville	7½	19	200	155
Conrey	9	18	150	185
Natoma	14	21	400	285
Folsom	13½	20	300	202
Boston & Idaho	15		300	285 ?
Conrey	17	22½	550	460

These are all close-connected chains, ordinary digging.

However, should one of the buckets in a bucket chain encounter a boulder of larger size than it can handle, the demand on the motor is immediately increased, and may even cause the motor to pull out if no protective devices are provided. Also, if the buckets run into particularly sticky clay in the course of their digging, the load on the motor may be very much increased, and as such a condition is seldom momentary, the continuity of the overload may burn out the motor unless the speed of digging is reduced.

In addition to these requirements, during digging the motor drive must also be capable of revolving the bucket chain slowly at no load for the purpose of repairing the buckets, inspecting the chain, and similar work required for the purpose of mechanical maintenance.

The bucket chain is driven through a hexagonal spindle at the top of the ladder, over which spindle the buckets pass. Each one of the flat sides of this spindle or tumbler, as it is termed, engages with a corresponding flat side on the under side of the bucket, and the drive is accordingly a positive drive, just like any chain drive would be. If the tumbler turns, the bucket chain has got to move or break. It cannot slip. An adequate and successful method of transmitting power from the driving motor to the tumbler has been the source of considerable study by dredge designers the world over.

Belt Versus Gear Drive

The tumbler shaft usually carries two pinions, one on each side, which engage with two gear wheels carried on a common shaft. This shaft is connected through an adjustable slipping friction to another drive shaft by means of gearing, and the motor drives the last-named shaft. It may be either belted or geared to this shaft. Belting the motor is, of course, the easier on the electrical apparatus, but on the other hand, has certain disadvantages. A large and expensive belt is required on account of the tremendous torques involved. There are sometimes difficulties due to maintenance, because of the moisture that is often present on board a dredge. The belt sometimes slips just when maximum torque is wanted. Occasionally, under the heavy stress due to the slipping friction having rusted, a belt will break. Also, a belt transmission for the transmission of the torques involved, takes up considerable space, and space on a dredge is valuable.

On the other hand, gearing, while economical in space and entirely positive in action, has the disadvantage that it imposes severe service on the electrical equip-

ment, in that every strain and every vibration from the bucket chain finds its way back to the revolving part of the motor. Flexible couplings have been tried between the motor and the driving gear, but without success. The large variations in torque encountered, sooner or later ruin any type of flexible coupling that has as yet been tried. The gear drive has, however, proved entirely successful where a motor has been secured that will adequately withstand the stresses. Of the two methods, belt *v.* gear drive, each has its ardent devotees, its advantages and its disadvantages.

Motors for Digging Service

From a consideration of the above, it will be seen that the motor required for digging service on an elevator dredge must have the following characteristics:

(*a*) It must be a varying-speed machine; and if in addition it can be made an adjustable-speed machine, this would be a considerable advantage.

(*b*) It must be capable of being revolved at light loads and very low speeds.

(*c*) It must be capable of developing a maximum torque, at any speed from zero to approximately full-load speed, of several times its normal rated torque.

(*d*) It must be capable of carrying, for prolonged periods of hard digging, a torque overload of approximately 25% at a speed reduction of probably 25 per cent.

(*e*) It must be of substantial mechanical construction, particularly as to shaft and bearings, in order to resist a heavy belt pull when belt drive is used, or repeated shocks of severe gear thrusts when gear drive is used.

(*f*) It must be reasonably efficient.

In order to obtain all of the above characteristics, it has often been suggested that a direct-current motor of the type used in steel mills, with possibly variable-voltage speed control, might prove advantageous for digging service on big gold dredges. However, every investigation that has been made (at least to my knowledge) of this matter has developed the fact that the losses in efficiency due to the conversion from alternating current to direct current, practically offset the advantages gained by more flexible control under the ordinary cycle of operation, and further, the first cost of such an installation is prohibitive, considering the ordinary life of a dredging venture. In this connection it might be stated that, while there are exceptions, the average dredge is about worn out at the end of 10 years, and will then require either complete rebuilding and remodeling, or will operate with so many shut-downs due to breakages and the like, that rebuilding or scrapping will prove most economical. Accordingly, any installation more expensive than ordinary must show a saving that will repay the extraordinary expense in 10 years, and this no combination of direct-current equipment has as yet been able to show.

Therefore, the only type of motor left available is the moderate speed wound-rotor induction type, and for the most successful application the motor should be designed with special reference to the work it has to do.

Type of Motor Recommended

From experience with the troubles of a dozen dredges, large and small, I would recommend specifications embodying the following: (1) The motor should be capable of carrying rated load continuously with a rise not to exceed 40° in any part. (2) The motor should be capable of developing a torque 25% in excess of its rated full-load torque, at a speed of 75% of its synchronous speed, for a period of two hours, with a rise not to exceed 55°. (3) The motor should have a maximum torque and a starting torque of not less than 2.5 times its full-load torque. (4) The shaft shall be of such material and dimensions that strains due to the developing of maximum torque shall not appreciably affect the dimensions of the air gap on any side of the motor. (5) The bearings shall be designed to resist an upward thrust, and shall preferably be of the design known as rolling-mill bearings furnished with stud bolts and lock nuts, instead of the usual design employing cap screws. (6) The lubrication of the bearings shall be adequate. On motors of 200 hp. and over, at least two oil rings per motor bearing are recommended. On motors of 500 hp. and over, the use of gravity feed lubrication should be considered.

The problem of control of large motors used for digging service on gold dredges would be more simple if direct-current motors could economically be used. As, however, their use is impractical, the control for alternating-current motors that most nearly approaches direct-current control is desirable. The control must permit reversing the direction of the motor, principally to permit the bucket line being backed away from obstructions. For service during the repair of the bucket line, small variations in speed should be obtainable, particularly at part loads. A control permitting continued running at low-speed points is particularly necessary.

Magnet-Switch Control

For small motors on little dredges, say employing a digging motor of 100 hp. or less, the ordinary drum-type controller proves adequate. For larger installations, a combination of magnet switches controlled by a master controller has been used in a large number of installations; but for the larger motors the ideal control seems to be the liquid rheostat.

Magnet-switch control has been used satisfactorily on a considerable number of dredges employing digging motors as large as 400 hp. The large fleet of big dredges operated in California by the Natomas Consolidated mostly employ magnet-switch control on dredges having digging motors of 300 hp. and larger. It has, however, several distinct disadvantages for dredge service. The principal disadvantage is that a limited number of definite points only are available with this type of control, unless the number of magnet switches in

the secondary circuit is made large, which in turn makes the controller inordinately expensive. Therefore, small variation in speed particularly at light loads, is not available with this type of control, and in order to obtain slow movement of the bucket chain it is customary to start the motor and then plug it, with consequent strain on all mechanical parts, as well as wear on the control contacts. Further, this type of control does not allow the dredge operator to pick out any particular speed at which he desires to run. He can only pick a particular point on the controller, and the corresponding motor speed will depend on the torque being exerted by the motor.

Another disadvantage of this type of control is the tremendous amount of resistance required for a large motor, as the resistance must be sufficient in amount to permit very low motor speeds at light loads, and large enough in capacity to permit continuous operation at reduced speeds with heavy torques. This makes a bulky resistance, and unless the resistance is large enough there is considerable danger from overheating of the grids starting a conflagration.

Liquid Rheostat Control

The liquid rheostat for digging-motor control has, on the other hand, none of the disadvantages of the magnetic switch control. There are no definite steps, and the speed of the motor may be varied by infinite gradations. The operator simply moves the rheostat handle until he obtains the speed he desires. In other words, he does not work for any particular point on the rheostat, but works simply with the idea of getting the speed he wants. For large motors, the liquid rheostat and its accessories take up much less room than would a corresponding magnetic switch control and its attendant resistance, and there is never any danger of the electrolyte used (water and common washing soda) causing a conflagration.

However, the liquid rheostat for use on dredges must be modified from the forms commonly used for hoist service and the like on land. The first liquid rheostat installed in dredge service was on one of the Natomas dredges with a 400-hp. motor, and while it was operative, it was not entirely satisfactory, because certain essential details of design and application were overlooked. A similar liquid rheostat on which these details have been given due attention is now being used on one of the dredges of the Conrey Placer Mining Co., and has been quite successful and satisfactory in operation with a 550-hp. digging motor, which I believe is the largest digging motor on any elevator-type gold dredge in operation today anywhere.

In order to keep down the size of the liquid rheostat for this work, it is practically necessary to provide some means of artificial cooling for the electrolyte. Usually this is accomplished by circulating cooling water through the coils in the rheostat tank. On the Natomas rheostat the mistake was made of pumping water from the pond in which the dredge floats through these cooling coils. Due to the operation of the dredge, this pond water is usually pretty muddy, and often carries a large percentage of solids in the shape of silt. At Natoma this silt coated the inside of the cooling pipes, thus reducing their effectiveness and eventually clogging them up, necessitating a shut-down while they were blown out with compressed air. Shut-downs on a dredge cost money, because to realize the greatest return on the investment the dredge must be digging all the time. Therefore, this feature made the Natomas rheostat undesirable. At the Conrey Placer Mining Co.'s property the cooling system consists of a series of pipe coils immersed in the pond, and the electrolyte is pumped from the rheostat tank through the coils and back again, instead of pumping pond water up to the tank and through the coils installed therein. There has never been a shut-down on the Conrey dredge due to the rheostat or its cooling system. The motion of the dredge in the pond is sufficient to keep silt from settling on the cooling coils.

Another point that was overlooked in the Natomas installation was the fact that dredges swing, and often rock considerably. This causes the electrolyte to splash out of the rheostat. Usually such loss by splashing was replaced by pouring in additional water, but this, of course, changed the density of the electrolyte and caused the operators some trouble. On the Conrey rheostat, baffle-plates and enclosing covers were supplied, which effectually prevented any splash.

Another trouble that was experienced at Natoma was that, due to deficiencies in the cooling system mentioned above, the electrolyte very often attained a high temperature during hard work, which caused excessive evaporation. Under certain conditions this evaporation was so great that the annoyance and expense of bringing the amount of fresh replacing water required on the dredge and filling the rheostat was considerable. This trouble has been obviated at the Conrey installation by having an adequate cooling system.

All in all, it may be said that for large digging motors of say 350 hp. and more, the liquid rheostat makes an ideal method of control, provided the rheostat is of adequate mechanical construction for the service and is provided with a proper and sufficient cooling system. Both liquid rheostat and magnet switch control may be arranged to give the same advantages as to protection against acceleration at too high a rate and against excessive overload due to sudden changes in speed.

Small Economies Necessary

It will probably be gathered from the above remarks that the successful application of electrical apparatus to gold dredging operations depends on a multiplicity of details, each of which may be of comparatively minor importance in itself, and this is true. With the areas that are now still available for dredging, a multitude of small economies must be practised in order to make the process commercially successful. When it is considered that many dredges dig for about 4 to 5c. per

cu. yd., and that the gold content of the ground often runs as low as 7c. per cu. yd., it can readily be seen that a matter of 1c. economy or waste may make or break the concern doing the dredging. Therefore, maintenance deserves consideration. But most of all, freedom from shut-downs is of prime importance. The dredge cannot make money while it is not digging; but interest, not only on the money invested in the dredge, but on the money invested in the purchase price of the land that is being dredged, goes on just the same, and therefore stoppages must be avoided at any reasonable cost, and this should be particularly borne in mind in the selection and application of the electrical apparatus and its control.

A digging motor that may be of sufficient capacity, but cannot be adequately controlled, may break a bucket chain and put the dredge out of business for 24 hours. Ordinarily, dredge operators figure on operating 24 hours a day, 365 days a year; and a fair average is to expect the dredge to be actually performing its operations for 85% of the total time.

On account of the high load factor, and on account of the comparative uniformity of a large percentage of the load, as well as on account of the comparatively large blocks in which the power is purchased, dredges make a particularly attractive load for hydro-electric central stations, and a few figures as to the power consumption of dredges may be of interest in this connection.

Moderate size dredges with buckets of about 5 to 7.5 cu. ft. capacity will handle from 60,000 to 100,000 yd. per month, at a power consumption of from 1.25 to 1.75 kw-hr. per cu. yd. Larger dredges with buckets up to 15 cu. ft. capacity will dig from 125,000 to 250,000 cu. yd. per month, and will take from 1 to 1.5 kw-hr. per cu. yd. The large dredge of the Conrey company, mentioned above, which has buckets of 17 cu. ft. capacity (I believe the largest in the world), has handled 520 cu. yd. of material per running hour. Including delays, this means 325,000 cu. yd. per month. Handling material (heavier than usual) weighing 3000 lb. per cu. yd., its power consumption was 1.28 kw-hr. per cu. yd. The above figures are total power taken by the dredge for all purposes. The power taken by the digging motor is about 40%, on an all-day average, of the total power. From such test results as are available, the power for digging seems about proportional to the yardage dug; that is, the kilowatt-hours are proportional to the yardage handled times the number of hours during which it was dug.

Tube-Mill Tonnage Calculation

By NOEL CUNNINGHAM

It is often difficult to determine the tonnage actually being handled by tube-mills working in closed circuit with classifiers. Where either tube-mill feed or discharge can be deflected and weighed for short periods, it is still a quite inexact determination, as an accurate moisture sample is essential, and where a portion of the pulp is cut out of the flow and weighed, if the amount is sufficient accurately to determine weight of total flow, it is next to impossible to get a close sample for moisture. In any case, only by averaging a number of weighings and moisture determinations can data of any value be obtained.

The following method is, I believe, original with myself, and allows a close determination of tonnage from four screen tests which are often either daily or periodic routine. The four samples required for these screen tests are: (a) battery discharge; (b) tube-mill feed; (c) tube-mill discharge; (d) classifier overflow.

The object of the calculation is to determine the ratio of dry tons tube-milled to dry battery tonnage. The calculation is based upon the fact that the minus 200-mesh material coming to the classifier is equal to the minus 200 which leaves the classifier.

Let a = per cent –200 in the battery discharge.
b = per cent –200 in the tube-mill feed.
c = per cent –200 in the tube-mill discharge.
d = per cent –200 in the classifier overflow.
B = battery tonnage dry.
T = dry tons tube-milled.

Now the –200-mesh material coming to the classifier is that in the battery discharge (aB) plus that in the tube-mill discharge (cT), while the –200 material leaving the classifier is that in the tube-mill feed (bT) plus that in the classifier overflow (dB), hence:

$$aB + cT = bT + dB$$

and $\frac{T}{B} = \frac{d-a}{c-b}$ = ratio dry tons tube-milled to dry battery tonnage.

Thus knowing the dry tons passing through the battery daily, the dry tons actually tube-milled daily can be readily calculated from the routine screen tests.

It is interesting to study the limits of this ratio in practice. I should say in a general way that the –200 in modern fine-grinding plants for the four screen tests entering into the above calculation would lie between the following limits:

	Per cent –200. Min.	Max.
Battery discharge	10	30
Tube-mill feed	2	8
Tube-mill discharge	35	60
Classifier overflow	60	90

The lowest value of $d - a$ within these limits would be 30, and the largest value of $c - b$ would be 58; hence within the above limits, tons tube-milled could never be less than half of battery tonnage. In the same way, the highest value of $d - a$ within the limits above would be 80 and the lowest value of $c - b$ 27, or the maximum tonnage tube-milled within the above limits could not be over three times battery tonnage. Generalizing, I should say that for mills where tonnage is being pushed this ratio would be about 1.75, and never under 1.

Electrolytic Zinc—the Reed Process

By E. H. LESLIE

In the development of modern metallurgy, one of the chief stumbling-blocks has been the treatment of certain zinc combinations which have been unamenable to all known metallurgical processes. The solutions proposed for this problem have been many, and the failures have been about as numerous as the proposals. The Reed process, which has been experimented with on a semi-commercial scale for the past year or more at Palo Alto, California, is an electrolytic method of zinc reduction, the technique of which method has been fairly well worked out in so far as the reduction of the zinc is concerned, but those economies of operation so essential to commercial success of the process are still in course of development. The Company secures a high extraction from the material carrying the zinc in the form of a solution of zinc sulphate ($ZnSO_4$), and from this solution recovers the zinc in metallic form with the aid of electricity. These features have passed the experimental stage. The operations have now been conducted continuously for more than three months. There is no doubt but that a material reduction in operating costs will be effected by large-scale operations and the improved equipment necessary for such work.

It will be the purpose of this article to discuss the metallurgical process and *modus operandi* rather than production costs and commercial possibilities; in that with the present state of development of the process but little more than a guess can be made as to what the possibilities of the process are, and the present work is being confined to small-scale operations for the purpose of determining the refinements necessary for most economic procedure.

Electrolytic zinc processes are not new, but have been fraught with many difficulties owing to the inamenability of zinc to electrolization in cells on a commercial scale; impure solutions, formation of excess sulphuric acid, spongy zinc, and lack of capacity have been real impediments to its commercial application. The process as being conducted at the Reed Zinc Company plant at Palo Alto presents many novel features and has overcome many of the difficulties of the earlier metallurgists who have worked on the subject. As a basis for the present process, it may be said that the electrolytic process which was patented by Carl Hering, of Philadelphia, has been used. This process has been modified and changed by Messrs. Reed and Leach and brought to its present state of development, which is one of promise and at least a long step toward a commercial electrolytic zinc process.

In electrolytic processes in which the reaction at one electrode is not the exact reverse of that at the other electrode, there is a gradual and progressive change in the electrolyte. This is due to the fact that something is either added to or extracted from the electrolyte or formed or decomposed in it, thereby changing its composition or concentration. In such cases it may happen that the cumulative change thus produced in time interferes with the proper continuance of the desired electrolytic process.

The object of the Hering process is to provide means by which such objectionable cumulative changes in the electrolyte may be prevented, thus enabling the desired process to be continued. This is accomplished by using an electrode of such nature and material as to combine chemically with the objectionable ingredient as it is formed in the electrolyte, thereby rendering it inert as far as the electrolyte is concerned, and thus preventing the latter from being contaminated. In many cases the

DIGESTER ABOVE THE VATS.

objectionable ingredient which is thus removed from the electrolyte is a useful product, and the Hering process further contemplates the recovery of this ingredient by removing the electrode with which it has combined and passing the reverse current through it in a second electrolytic process. Thus when it is desired to extract electrolytically a positive ion—say a metal—from a solution containing the same, unless the anode is one which continuously replenishes the solution with the metal, which is being thrown down at the cathode, the negative ion with which the metal is combined may remain in the solution and thus cumulatively hinder the further extraction of the metal. To prevent this setting free and accumulation of the negative ion formerly in combination with the metal, Hering's process employs the use of an anode of such nature and material as upon the passage of the current will chemically combine with this ion to form an insoluble compound which adheres to or unites with the anode. After the anode has been acted upon in this manner to its full capacity, it may be removed from the solution and placed in another electrolyte and subjected to the action of a current in the reverse sense of that originally employed, thus setting free the combined ion and restoring the plate to its original condition.

In extracting zinc from a solution of zinc sulphate in the presence of an excess of sulphuric acid, an accumulation of the sulphate radical from which the zinc is separated (which forms sulphuric acid when insoluble electrodes are used) hinders the efficient extraction of the zinc. This is because sulphuric acid, being less stable than zinc sulphate, electrolyzes more readily, setting free hydrogen at the cathode with a consequent loss of energy, and also tending to form a loose and spongy, instead of a dense and adherent, deposit of zinc on the cathode. Furthermore, the presence of sulphuric acid formed at the anode tends to redissolve the zinc.

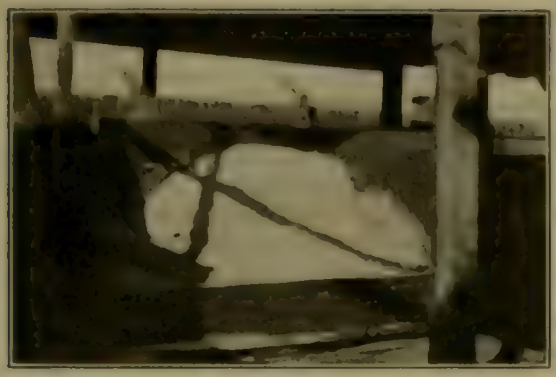
These reactions are even more apparent when nearly all of the zinc has been extracted from the solution, as there is then present a relatively large per cent of sulphuric acid. With the Hering process there is employed in the electrolyzing of the zinc sulphate solution an anode of spongy lead, the cathode being of any material suitable for the deposition of zinc. The sulphate radical, as it is set free by the electric current, then combines with the spongy lead of the anode, forming insoluble lead sulphate, which adheres to the anode and can be removed with it from the solution. After the anode has thus been completely sulphated, it is placed in another cell containing water or any other desired electrolyte, and upon being constituted a cathode by a current in the reverse manner, the sulphate radical is again set free with the formation of sulphuric acid if water be the electrolyte. The spongy-lead anodes must, of course, be of a capacity corresponding with the quantity of zinc deposited on the cathode in the first operation, or else they must be replaced by new plates from time to time. Their exhaustion is indicated by a rise of the voltage between the terminals of the electrolytic cells. It is to be noted that in the first operation, during which the zinc is extracted, the voltage required to obtain the zinc is about 1.6 volts less than that theoretically required to extract zinc from its sulphate, as the sulphating of the lead anodes gives rise to a direct electromotive force of this magnitude. This, however, in a continuous process, is no gain, as a counter electromotive force of the same amount must be overcome by the current from the external source in the subsequent operation when the anodes are restored to their original condition.

This is the Hering process of electrolization upon which an endeavor is being made to produce zinc on a commercial scale from ores and smelter by-products which have been inamenable to the recognized processes of zinc metallurgy.

Work at Palo Alto

At the present time the Palo Alto plant is concerned solely with treating a bag-house product from the Mammoth smelter at Kennett. A large tonnage of this material has been accumulated during the past years, and to date has baffled every effort of the metallurgical en-

TREATMENT VATS.



ZINC SULPHATE AFTER CRYSTALLIZATION.

gineer. The composition of the bag-house dust or 'fume,' as it is termed locally is as follows:

Gold, ounces	0.05
Silver, ounces	11.00
Copper, per cent	1.1
Iron, per cent	5.0
Lead, per cent	8.2
Arsenic, per cent	6.2
Zinc oxide, per cent	14.6
Zinc sulphate, per cent	38.6

This material is delivered in freight cars over a turnout from the main line of the Southern Pacific to the plant, which is situated about three-quarters of a mile southwest of the western end of the Dumbarton 'cut-off' and about three miles east of the town of Palo Alto, California. The plant is convenient to deep water, railway, and the power-lines of the Pacific Gas & Electric Co. Its proximity to San Francisco, the smelters of California, and west coast mines makes the location favorable for such a project. As cheap power, however, will be the governing element of the commercial success of large-scale operations, this will be the primary and determining factor of location for such plants.

The 'fume' as delivered at the plant is stored in bins from which it is elevated in 250-lb. buckets to the charging floor. Here it is dumped through a chute into the digester, which is a unique device made after designs by C. J. Reed. It consists of a cylindrical vat, 6 ft. diameter and 12 ft. long, made of wood and about which there is fastened 'T' rails of standard gage. The digester is supported by these rails, which impinge on four car wheels—being a converted street-car truck—and when put in operation cause the digester to revolve. The inside is fitted with four longitudinal baffles which give the pulp a thorough agitation. The digester and driving mechanism is mounted on a second truck which moves on rails by means of a motor and trolley over the eight treatment tanks.

The 'fume' is charged through a manhole in the digester similar to that used in boiler construction, and is here mixed with a weak solution of sulphuric acid of 1.20 sp. gr. A lead-lined centrifugal pump is used for elevating the acid from the acid tank to the digester. When the charge, which at capacity is about 150 cu. ft., has been put in the digester, the manhole is closed and the digester revolved by the driving mechanism, and the 'fume' treated for a period of about three hours. Before discharging, the charge is sampled and 'fume' or acid added according to the state of acidity. The charge on being discharged must be acid for best results, as this assumes the almost complete extraction of the zinc. If too acid, more 'fume' may be added.

When digested the charge is moved over one of the 'acid' vats, of which there are five in this series of eight treatment vats, and dumped. Here it is allowed to settle for 3 or 4 days, when the solution is decanted. The settling and decanting is a slow process, and for this reason filtration can and is about to be substituted at this point in the procedure. The solution is then returned to the digester and more 'fume' is added in order to neutralize the acid present and precipitate a part of the copper, iron, and other impurities.

The second digestion occupies about three hours, after which a part of the solution is decanted from the digester and the remainder settled, decanted, and filtered in the tanks. This second operation is much faster than the first, it being only necessary to allow the solution to stand over night. The solution is now pumped by a monteju (what is known as an 'acid egg' in the Middle West) to the evaporating plant.

Residue from Digesters

The residue, as filtered from the neutral solution, is returned to the digester and here mixed with the next charge and so re-treated. The residue or tailing from the first acid treatment is discharged, dried, and will be eventually given a further treatment. Analysis of the residue or tailing is as follows:

Gold, ounces	0.06
Silver, ounces	19.1
Lead, ounces	26.3
Cu, per cent	2.75
SiO_2, per cent	10.9
Iron, per cent	11.8
Zinc, per cent	6.5
Sulphur, per cent	9.8
CaO, per cent	2.7

A glance at the above analysis shows the residue to be

EVAPORATION DEPARTMENT.

a valuable product and well worthy of further attention.

There are four pine tanks in the storage department of the evaporating and purifying department, one for solution and three for 'mother liquor.' From the solution tank the zinc-bearing solution flows by gravity to the evaporator.

Evaporating Department

The evaporation of the solution to the proper density for crystallization of the zinc as sulphate is done in a trough evaporator which is 40 ft. long, 2½ ft. wide, and has a depth of solution of 12 in. This trough is lead lined and fitted at one end with a Dutch oven fire-box in which crude oil is burned. In the top of the furnace are fitted three iron flues connected with three lead flue pipes which are of 4 in. diameter. The flue pipes are laid through the entire length of the evaporation trough and discharge the burned gases of combustion into the air. The process of evaporation is a slow one, it requiring about two days to evaporate 75 cu. ft. of solution. The present equipment is ample for the experimental work being done and the limited capacity of the plant, but with large-scale operations this department would be materially increased.

The process of crystallization is for the purpose of purification and is the last step in the purification process. Crystallization of zinc sulphate is performed in 8 lead-lined vats into which the solution from the evaporator flows by gravity. These vats are 8 ft. long, 4 ft. wide, and 3 ft. deep, inside dimensions. The vats are lead lined and across their width there are fitted thirteen wooden pieces spaced equi-distantly from one another, and from these bars there are suspended lead strips, there being 3 of these from each bar. These sheets of lead, upon which the zinc sulphate crystals form, are 10 in. wide and 3 ft. long, extending almost to the bottom of the vats.

The process of crystallization is continuous, one vat being cleaned up every day. The time required for crystallization is about eight days. In this process the $ZnSO_4$ crystallizes out first, forming on the lead strips to a thickness of from 1 to 2 inches. This salt contains 22½% of metallic zinc, which is removed from the plates and vats and stored in a bin for further refining. The 'mother liquor' is pumped back to the storage tanks and re-evaporated and again crystallized. The re-evaporation of the 'mother liquor' requires from 12 to 15 hours.

This process of purification has been found greatly to abet the subsequent electrolytic precipitation of the metal, and as such forms an important step in the process. As crystallized the zinc sulphate ($ZnSO_4$) is usually snow white, but sometimes tainted with arsenous salts and some copper.

The zinc sulphate is removed from the storage bin in a barrow and shoveled into a vat which is sunk in the ground, to permit of a gravity flow of the solution from the cell room. Here the zinc sulphate crystals are dissolved in the weak solution returned from the electric cells after extracting the zinc, and the solution thus formed is elevated by a small centrifugal pump to the purifying vat. Here a small amount of zinc dust is added and the charge agitated by air, in this manner precipitating the copper and other metals electro-negative to zinc, the process requiring about twelve hours. The purified solution is then filtered through canvas by vacuum and pumped to a storage tank. The solution as stored for the electrolytic refinery contains about 8 lb. zinc per cubic foot.

In the electrolytic plant there are 15 cells, 8 of which are 'charging' and 7 'depositing' cells, placed in alternate order. The charging cells are connected by lead pipes permitting a continuous flow of the solution, as are also the depositing cells. In the depositing cells a sponge-lead anode is used with an aluminum cathode. Upon the passage of the current through the zinc sulphate electrolyte, the zinc is deposited at the cathode on aluminum, and sulphuric acid at the anode. The acid combines with the lead, forming lead sulphate. The reaction which takes place is expressed by the following formula:

$$ZnSO_4 + Pb + \text{electric energy} = PbSO_4 + Zn$$

After deposition takes place, the sponge-lead anode of the depository cell with its lead sulphate coating is removed to the charging or acid cell, where it becomes the cathode with a lead 'dummy' for the anode. The current upon being passed in a reverse manner through this charging cell causes the lead sulphate, formed on the anode of the depository cell, to be reduced back to sponge lead, the reaction being as follows:

$$PbSO_4 + H_2O - \text{electric energy} = Pb + H_2SO_4 - O$$

Oxygen Recovery

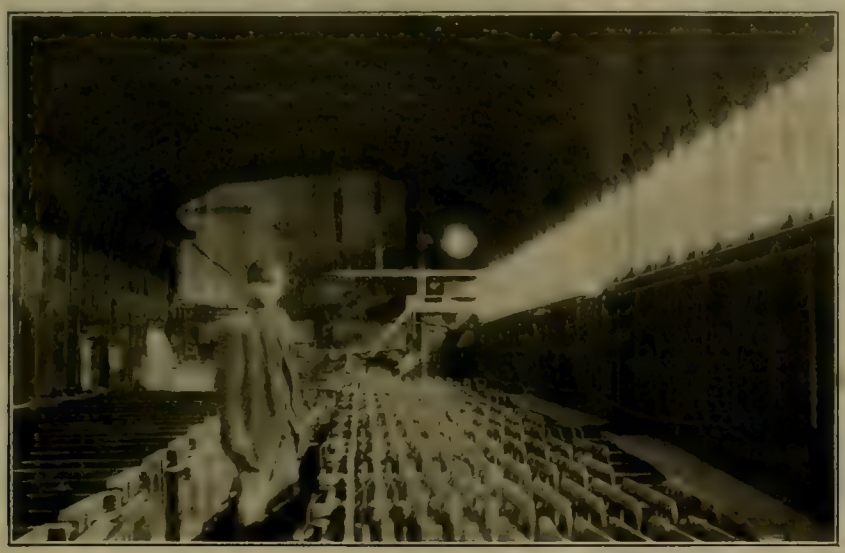
The Company controls patents for the recovery of the oxygen liberated at this state of the process, but the equipment for the recovery of this element has not been installed. In that there is about one-fourth, by weight, as much oxygen as zinc produced, it is believed that its recovery is of commercial importance. The lead 'dummy' used as an anode in the charging cell is gradually converted into sponge lead and may replace the sponge-lead anode in the depository cells. The deterioration of the anodes, however, is very slight. Some of the anodes have been in use for over a year and show no deterioration. They can scarcely be distinguished from new anodes.

The electrolytic department is fitted with a traveling crane moving over the cells and suspended from a track. A small hoist with attachment for gripping the plates of the cells is attached to the crane, and in this manner the transfer of plates from the depositing to charging cells and the reverse is greatly expedited. The current is supplied by the Pacific Gas & Electric Co. A small generator being used which is connected with a 25-hp. motor. Current is supplied to the cells at 350 amperes and 32 to 42 volts for the 15 cells. At the present time only 3 electros are being used in each cell, as no effort is being made to run the plant at capacity, and will

not until all of the refinements of the process have been determined.

The cell solutions as discharged from the cells by gravity are collected in sump tanks. The solution from the depositing cells, after passing through the 7 cells, flows to the weak solution tank, and the small trace of acid is here neutralized with scrap zinc. It is then conducted to another tank where the zinc sulphate crystals are added, and it is brought up to strength and returned to the electrolytic department for deposition. In the charging cells water is run into the first of the series, but with the formation of sulphuric acid in accordance with the reaction mentioned; the solution emerges from the last charging cell as what is termed locally 'strong acid.' This is used in the digester in the preliminary treatment of the ore.

The electrolytic zinc, as stripped from the cathodes after about 48 hours of deposition, is in plates of about $\frac{1}{8}$" in thickness and of a firm minutely crystalline texture. The sheets thus formed are melted and cast into



ELECTROLYTIC PRECIPITATION DEPARTMENT.

bars which are a very high-grade product averaging 99.88% zinc.

The process as installed has demonstrated that electrolytic zinc is well within the range of probability. It is being made with an extraction of 93% of the zinc content of the material treated; a marked advance in extraction over the smelting methods universally employed, and the product is a high-grade spelter of excellent quality. From a commercial standpoint the process is yet to be proved, and I am not able at this time to discuss in detail its commercial possibilities. The present plant and equipment is not a fair criterion by which to judge the possibilities of the process from a commercial standpoint. Large-scale production would embody some mechanical changes in the handling of the materials and solutions which would materially reduce the cost of production. The power question, power being the chief expense, is the important factor to be considered, and upon this, to a large extent, would depend the commercial success of the process. It will be understood that the process in its present state is being employed solely for the treatment of ores and smelter products which have been inamenable to all known metallurgical methods. E. R. Leach and his associates have been making a thorough investigation of its possibilities for the past year or more, and their efforts have thrown a new light upon the possibilities of electrolytic zinc extraction. The process is one that is full of promise as to possibilities and application. Its inventors and sponsors are to be congratulated upon the new technique which it has developed.

Miners' Health at Broken Hill

A commission of three has submitted an important report to the New South Wales parliament on various phases of industrial conditions in the lead-zinc-silver mines at Broken Hill. They recommended the following: (1) That no person suffering from tuberculosis be permitted to work underground. (2) All persons working underground be examined once in every six months by a medical officer appointed by the government. (3) No person be permitted to work underground unless he can read and intelligibly speak the English language. (4) That lead poisoning and its *sequelae* (results) be made diseases which are chargeable on the Miners' Accident Relief Fund. (5) Investigations be made as to the liability of miners at Broken Hill to pneumonia, and that compensation be given if this disease be found to be an added and exceptional risk of the miners' calling. (6) In mine air the maximum of CO_2 be 1%, and the minimum of oxygen 19%. (7) Provision be made on each level of any shaft to provide shelter from the cold air for those who are waiting to be hoisted to the surface.

Two dredges of the Orsk Goldfields Co., Russia, produced gold worth R.72,700 ($35,000) from 119,050 cu. yd. of gravel during October. Tributers also recovered R.15,300 ($7500).

Accommodation for certain employees at the Mt. Lyell mine is being provided. First-aid and rescue-work instruction has been started.

Electric Smelting in 1914

By ROBERT M. KEENEY

During the past year, smelting of ores in the electric furnace made notable advances in the clarification of several fundamental technical questions upon which the electric smelting of iron and zinc ores depends. The year saw the completion and operation of the largest electric iron-smelting furnace built up to date. Work was started on the first commercial electric zinc smelting plant to be constructed in the United States. The first aluminum plant to be built in this country since the expiration of the Hall patents was well under way at the close of the year. As a result of the high price of ferromanganese, caused by the European war, the one electric pig-iron plant of the United States started the manufacture of ferromanganese. There was also increased attention paid to the possibility of local manufacture of other ferro-alloys such as ferrochrome and ferrotungsten, because of foreign conditions. The lack of a supply of cyanide has resulted in one company, formerly a producer of sodium, renewing the manufacture of this metal in the electric furnace for later conversion to sodium cyanide.

The chief points of technical interest in which there have been important developments during the past year are the following: (1) The use of coke instead of charcoal as a reducing agent in electric smelting of iron ore; (2) the introduction of much larger units than heretofore built for the manufacture of pig iron, ferrosilicon, and calcium carbide in the electric furnace; (3) increased attention directed to the production of pig steel directly from ore in the electric furnace; (4) further progress made in the solution of the condensation problem in electric smelting of zinc ore.

Use of Coke as a Reducing Agent

In the early experiments on electric smelting of iron ore, at Livet, France, in 1904, and at Sault Ste. Marie, Canada, in 1906, coke was used as a reducing agent. With the small furnaces employed in both cases, coke seemed as advantageous as charcoal for a reducing agent in the electric furnace manufacture of pig iron. But as the first commercial development of electric iron smelting was in Sweden and California, where at that time charcoal seemed to be the cheapest reducing agent, little attention was paid to the use of coke for this purpose until recently, within the past two years. In Sweden there is no immediate need for a change from charcoal to coke; but it has become evident, just as in the production of blast-furnace charcoal iron, that the forests for the manufacture of charcoal are rapidly being depleted in spite of decreased consumption since the introduction of the electric furnace. At some time in the future, some reducing agent other than charcoal must be employed. With the electric smelting of iron ore in Norway, it was absolutely necessary to use coke for that purpose, because there are few forests in Norway. In California, it appeared at first that charcoal could be obtained cheaply and in quantity, but later when the wood had to be hauled from a distance, the cost increased to such an extent as to render imperative the securing of some cheap reducing agent. Coke is not as expensive as charcoal in most localities and can be obtained in greater quantity.

Where Coke Fails

Up to the beginning of 1914 a study of existing data and experience with coke in the electric smelting of iron ore would indicate that the only satisfactory reducing material for the smelting of iron ore was charcoal. The trial run at Trollhättan, Sweden, had shown that coke was not as suitable as charcoal for use in the electric shaft furnace. From the somewhat meager reports then existing regarding operation at Hardanger, Norway, with an electric shaft furnace of the Trollhättan type, the difficulties of that plant were commonly laid to the use of coke as a reducing agent. The work done in the low rectangular furnace at Heroult, California, also indicated that coke was not suitable for electric smelting.

Practically all authorities agree that the basic reason for the difficulties encountered in the use of coke in the electric furnace, is because coke is a much better conductor of electricity than charcoal, especially after it becomes hot. Hence, when coke is used, the resistance of the charge becomes lowered, and, as the smelting in the electric iron-reduction furnace is done by the heat produced by the resistance which the electric current meets in passing through the charge between the electrodes, more current is required to produce the same amount of heat.

The causes of the economic failure of the electric pig-iron plant at Tyssedal, Hardanger, Norway, which had ceased operation during 1913, were investigated by several commissions and engineers. The Norwegian electrometallurgical commission,[1] through J. H. L. Vogt and P. Farup, reported that the shaft furnace, the Trollhättan type, has proved a success with coke as a reducing agent as a result of the runs at Hardanger, which conclusion is contrary to the Trollhättan deductions with a similar furnace.

They state that while the operations at Hardanger were not economically successful, the cause should be attributed partly to the nature of the ores treated and partly to their low iron content, together with the unsatisfactory type of roaster used for agglomeration and poorly designed electrical machinery.

G. Odequist, in a paper before the Christiania Poly-

[1] 'Electrothermic Iron Ore Smelting in Norway,' *The Eng. & Min. Jour.*, July 25, 1914, p. 158.

teknik Forening, did not agree with the committee in its conclusions, but believed that the unfavorable results were due to the type of furnace, which, in his opinion, was not adapted to coke because of the greater variation in the electrical resistance in the furnace itself by the use of coke, owing to which the average load as well as the production is diminished. Also, he considers that the greater quantity of limestone needed to flux the coke ash increases the power consumption. Lindemann, a Norwegian engineer, lays the failure of the Hardanger plant to the fact that the furnace had never treated the sort of charge which would render smelting profitable. The briquettes charged crumbled in the furnace and the 'fines' were not properly agglomerated. In a review of the paper by Odequist, J. Harden[2] concludes that the failure of electric smelting at Hardanger was due to a variety of causes, but that the use of coke in the type of furnace employed was one of the more important factors.

FIG. 1. ELECTRODES IN HARDANGER FURNACE.

At the Tinfos Iron Works, Notodden, Norway, it is reported that pig iron is being made in the electric furnace with coke as a reducing agent. Four single-phase furnaces, each of 1250 kw. capacity, are installed at this plant in such a manner that one furnace is connected to each phase of a three-phase circuit with one furnace held in reserve. The charge is fed into the furnace around the electrode through two feeding shafts leading to a low rectangular crucible. The shafts are intended more for distribution of the charge in the crucible than for securing any reduction by the furnace gases. The current passes through an upper rectangular electrode, through the charge, and through the conducting carbon bottom. Coke is said to work satisfactorily in a furnace of this type. A similar plant has been recently built at the Ulefos Iron Works, Telemarken, Norway.

The Helfenstein furnace, which has three upper vertical electrodes, each suspended in a separate chamber of a low rectangular furnace with a conducting hearth common to all three chambers acting as the neutral point of a three-phase circuit, has given excellent results in the electric smelting of iron ores at Domnarfvet, Sweden.

In regard to the use of coke in this furnace, Helfenstein[4] states that the two essential conditions for successful smelting with coke are: (1) the tension in the smelting furnace must be lower, and the density of the current in the electrode must be higher; (2) the furnace gases must be removed after having passed through a comparatively thin layer of materials in the melting chamber. He considers that due to the existence of these conditions in his large furnace, it is possible to substitute coke for charcoal as a reducing agent.

As a result of 90 days' operation of the low rectangular furnace of the Noble Electric Steel Co. at Heroult, California, with coke as a reducing agent, J. Crawford[5]

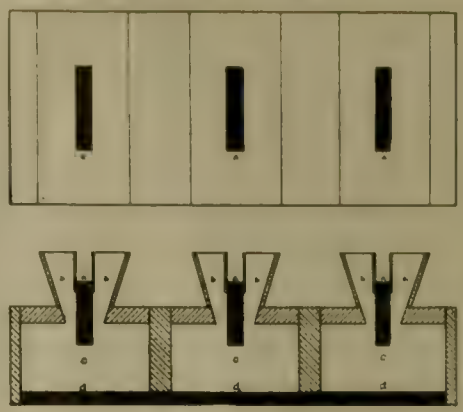


FIG. 2. ELECTRODES IN HELFENSTEIN FURNACE.

has drawn the following conclusions: (1) any ordinary grade of coke, by crushing it, can be used satisfactorily from both a metallurgical and an electrical standpoint to produce any normal grade of pig iron; (2) if the coke is of the proper size when it reaches the smelting zone, operations may be carried on with as high voltage, low current densities, good power factor, and as cool a roof when using coke as when using charcoal; (3) the power consumption per unit of production is higher with coke than with charcoal, but the increase is due to the extra amount of slag made; (5) the carbon consumption per unit of production is higher with coke than with charcoal; (5) except for the somewhat more open grain, no difference has been noted thus far in the physical characteristics of iron made with coke, and iron made with charcoal; (6) crushed coke has a tendency to make the charge hang in the furnace, which might prohibit its use in a shaft furnace. A mixture of 15 to 25% of lump charcoal with the coke appears to prevent the hanging of the charge.

[4]Helfenstein, A., 'Large Electric Furnaces for Pig Iron. The Helfenstein Furnace at Domnarfvets.' *Iron and Coal Trade Review*, April 3, 1914, p. 505.

The conclusions of Crawford, which are the result of some of the most extensive work yet done on the subject, are summarized in the statement that coke has nothing to recommend it over charcoal for an electric furnace reducing material excepting the difference in price.

Shaft Furnaces and Crucible Furnaces

As a result of the work during 1914, with coke as a reducing agent in electric smelting of iron ore, it is evident that considerable progress has been made toward the solution of the problem. The so-called shaft furnace of the type built at Trollhättan and Hardanger does not appear to be so well adapted to the use of coke in place of charcoal as is the low rectangular furnace of the Helfenstein, Tinfos, or California types. Pig iron can be produced commercially under the most favorable local conditions in a shaft furnace, but not as economically as in the crucible furnace. The power consumption and the carbon consumption will be higher in the shaft furnace, but technically and commercially under the best conditions, pig iron can be made in this type of furnace using coke as a reducing agent.

There is little agreement as to the cause of the failure of the Hardanger plant, but it cannot be entirely assigned to the use of coke as a reducing agent. The conditions were unfavorable from the start; a poor grade of ore which requires roasting was being smelted; and the type of roaster used was very unsatisfactory both in its mechanical operation and in the product it produced. There appeared to be several things in both the business and technical management of the concern which might have been improved considerably. Apparently in the erection of the works, little allowance was made for the fact that even in the operation of an electric pig-iron furnace using charcoal, the process is very young and comparatively undeveloped; and that with the unknown effect of coke considerable experimental work might be necessary. Judging from the character of the buildings erected, the Company must have had a considerable overhead charge to carry.

During the year it has been established beyond question that better technical results are obtained with coke as a reducing agent, when the low crucible furnace of the Helfenstein or Tinfos type is used rather than a furnace of the Swedish type. This is emphasized by the early experiments with coke at Trollhättan in a furnace of the latter type, the difficulties at Hardanger, and the successful operation of the Helfenstein furnace at Domnarfvet with coke, and the furnace at Tinfos. The difficulties experienced with the so-called shaft furnace are not due to the effect of the shaft resulting in the impossibility of quick removal of gases, or any other effect produced by the shaft itself, but are due to the arrangement of the electrodes in the crucible of the furnace. In the Trollhättan furnace the electrodes are grouped at the base of the shaft around a circular crucible. As there is no bottom electrode of any sort in the furnace and the ends of the electrodes are practically in the same horizontal plane, the current must pass between them in this horizontal zone. When smelting conditions are established in the furnace, the process is advanced to the same point throughout this horizontal zone. As the electrodes are high in the crucible where little reduction has completely taken place, considerable unconsumed carbon accumulates in this zone. Coke has a much greater electrical conductivity than charcoal when hot. Hence, when coke is charged instead of charcoal, the voltage of the furnace gets low, resulting in decreased power factor and a higher power consumption per ton of ore smelted.

The remedy for this difficulty is an arrangement of the electrodes such as to make the current pass through all of the lower smelting zones of the furnace which contain the charge in different stages of reduction. Thus if the current passes through one upper electrode, through the charge and through the furnace bottom, a simple type of such a furnace being the Siemens furnace, it passes from top to bottom through the following smelting zones—a mixture of partly reduced ore and coke; a zone of completed reduction with the metal in a pasty unmelted state; the slag zone; and in the bottom molten metal. The result of an accumulation of coke in one zone of a furnace of this type is not as noticeable as the current has to pass through all of the smelting conditions of the furnace. A furnace of this type in which the current is actually conducted away from the bottom of the furnace with cables or bus-bars, has the disadvantage of a decreasing electrical efficiency and power factor with increase of size so that furnaces of much over 1000 hp. are not economical. That the shaft has nothing to do with the coke problem is further shown by successful smelting with two shafts on the Tinfos furnace, which has a conducting bottom and vertical electrode suspended between the shafts. The results at this place show that the success of the low crucible type has not been due so much to the absence of a shaft in some other cases as to the arrangement of the electrodes in the shaft.

The Helfenstein Furnace

In the Helfenstein furnace the objections to the Tinfos type of furnace are overcome, that is, a limitation of size due to conducting current through the hearth and away from the furnace. The current in the Helfenstein furnace at Domnarfvet passes down through the charge from suspended electrodes, each in its own smelting chamber, and while the furnace bottom acts as a conductor of current between the three smelting chambers of the furnace, it has no cable or bus-bar connections leading to the source of power. By connecting the furnace to a three-phase circuit in this manner, the difficulties of leading large amounts of current from a furnace bottom are not experienced with the consequent limitation in size of furnace, but it has the advantage of passage of current through the whole charge, insuring higher electrical efficiency when smelting with coke than in the furnace with a horizontal arrangement of electrodes.

The rectangular furnace of the Noble Electric Steel

Co has the horizontal arrangement of electrodes. Mr Crawford states that coke if finely ground can be used as a reducing agent with satisfactory results. From this it does not appear that coke would prove as satisfactory as charcoal in the furnace used at Heroult. The fine crushing of coke has not been necessary in the Helfenstein furnace, and this further indicates that the arrangement of the electrodes is the chief factor of the problem. The early experiences in California with coke in a furnace of this type were apparently not successful, for Crawford states that the efficiency of the furnace is decreased when coke is used instead of charcoal. Further evidence of difficulties with coke at Heroult are shown by the decision to use a mixture of half charcoal and half coke in the manufacture of ferromanganese,[7] which was undertaken at this place in the fall.

While coke is being used commercially at Domnarfvet and Tinfos for electric smelting of iron ores, and the possibility of its use in the California furnace has been demonstrated in a trial run, it is best to reserve definite conclusions until more developments occur, but the problem is well on the way to a satisfactory solution, judging from the results of the past year.

The Capacity of Electric Smelting Furnaces

During 1914 information was made public regarding the large Helfenstein furnace which started production of pig iron at Domnarfvet, Sweden, in May 1913. This furnace marks a great advance in the size of electric pig-iron furnaces. Previous to this time the largest pig-iron furnaces were those of the Trollhättan type of 3500 hp. capacity. The Helfenstein furnace at Domnarfvet was built for a power capacity of 10,000 to 12,000 hp., but owing to the high frequency of the electric current produced at Domnarfvet, 62 cycles, the power input was reduced to 6000 to 8000 hp. when smelting with charcoal and 5000 to 5500 hp. when using coke. The power was reduced with this high frequency in order to keep the power factor as high as 0.8 if possible, which under the circumstances was difficult, 25-cycle current being preferable for electric furnace work.

While electric furnaces of as large as 6000 to 10,000 hp. capacity have been operated for the manufacture of ferrosilicon and calcium carbide, the size attained in the Helfenstein furnace is undoubtedly a big advance in electric smelting of iron ores. The furnaces of the Trollhättan type with electrodes grouped around a circular crucible, are limited in size by the difficulty experienced in making carbon electrodes over 30 in. diameter, and also by the fact that the diameter or thickness in case an electrode of square cross-section is employed is limited by the distance between the edge of the crucible and the edge of the shaft. If a furnace of large tonnage of the Trollhättan type is built, the necessary power cannot be introduced into it by simply increasing the size of the electrodes and using built-up electrodes, but it must be done by increasing the number of electrodes suspended around the crucible. This leads to numerous complications resulting in lowering the electrical efficiency of the furnace. The limitation of size of electrode thus limits the power and smelting capacity of the furnace. In the case of a rectangular furnace having the electrodes suspended in the centre of the crucible and feeding shafts on both sides as in the case of the Helfenstein and Tinfos furnaces, there is practically no limitation as to the possible size, because increase in size simply means a longer furnace with electrodes to correspond. It is similar to the increased capacity of the long Mathewson copper blast-furnace over the shorter length furnaces.

The question of increased size of the electric pig iron furnace is very important if the electric furnace is ever to be in the class of the modern blast-furnace in regard to output. An electric furnace with a power input of 3500 hp. should produce per 24 hours on the basis of a power requirement of 2000 kw. hours per ton of pig iron, 30 tons of pig iron, while a 10,000 hp. furnace would produce about 90 tons in the same period. Compared with a blast-furnace output of 400 to 500 tons per day, the electric furnace capacity up to date is small, but the rectangular design of furnace offers greater opportunities of approaching blast-furnace size than does the circular furnace. Although the large electric furnace reduces the cost of production accordingly, the actual thermal efficiency is not much greater than that of a modern 1000-hp. smelting furnace.

Production of Steel Directly from Ore in the Electric Smelting Furnace

Recent experimental work I have conducted[8] has shown the possibility of producing steel of various percentages carbon and low percentages impurities directly from ore in the electric furnace. In a discussion of these results, J. Crawford[9] has summarized his conclusions as a result of experience in the electric furnace manufacture of pig iron at Heroult, California, by stating that although pig steel may have signal advantages over normal low-silicon pig iron for steel making, American steel makers will probably be found 'from Missouri' and will have to be shown. While there is a considerable economy in both carbon and power in making low silicon iron as against high silicon iron, the carbon does not approach in practice the low theoretical consumption. Pig steel of 2.20% maximum carbon when made in either the rectangular furnace or the shaft furnace requires carbon in excess of the theoretical to prevent excessive iron losses in the slag.

E. Humbert[10] and A. Hethey have performed large

[10]Humbert, E., and Hethey, A., 'Fabrication direct de l'acier.' *Journal du Four Electrique et de l'Electrolyse*, July 1, 1914, p. 843.

scale experimental work on the direct production of steel from ore, using a single-phase Heroult steel furnace of 6 tons per charge capacity. Several runs were made in the furnace on magnetite and silicious iron ores with coke as a reducing agent. According to the results of this work the authors consider that the direct production of steel in the electric furnace has many advantages over the standard practice of steel manufacture. While the process is simple and produces a high-grade product if desired, it may be expensive—the chief factor in this being the cost of power.

Pig steel for castings is now being manufactured directly from ore in an electric furnace at the foundry of the Moffat-Irving Steel Works, Ltd., of Toronto, Canada. A 300-kw. three-phase furnace is used which has a tilting crucible set under a stationary shaft. The process is intermittent. Fine ore and flue dust are smelted in the furnace.[11]

The cost of production of pig steel from ore in the electric furnace is, of course, the main stumbling block to the success of such a process. As yet not enough practical work has been done to give conclusive figures. All work to date has been almost entirely experimental, and while it has shown that the metallurgical difficulties are not impossible to overcome, few data as to actual cost are available. While there are few districts where pig steel could be produced as cheaply in the electric furnace as steel produced by standard methods, in some places and for foundry work it is probable that steel castings could be made more cheaply directly from ore by this process than in a combustion furnace. At any place where there is a market demand for steel locally, and pig iron can be made in the electric furnace at a profit, the steel ultimately produced would be cheaper, if made by the electric reduction of iron ore to pig steel, followed by refining in another furnace if necessary, than if the product of the electric reduction furnace was pig iron to be subsequently converted to steel in another furnace.

Condensation of Zinc in Electric Zinc Smelting

The most complete statement of the status of electric zinc smelting which was presented during the past year was that of W. R. Ingalls.[12] Ingalls concludes that the difficulty in the efficiency of condensation of the zinc vapors in electric smelting of zinc ore is not due to the condensing apparatus, but that the trouble really originates in the furnace itself, and that given the proper conditions in the furnace, condensation is effected without special difficulty. If electric smelting is made a two-stage process instead of a continuous process, satisfactory condensation as metal instead of blue powder will be obtained. In other words, the high amount of carbon dioxide gas given off as in the ordinary retort during the driving off of hydrocarbons and decomposition of carbonates, must be replaced by a carbon monoxide atmosphere as in the second stage of retort smelting, when reduction and distillation are accomplished. In considering the two kinds of blue powder formed in zinc condensation, Ingalls distinguishes between the meltable blue powder resulting from improper physical conditions, and the non-meltable powder due to improper chemical conditions. The un-meltable blue powder in electric smelting must then be due to the formation of larger amounts of carbon dioxide in the electric furnace than in the retort, which causes oxidation of the zinc in condensation.

The Johnson Furnace

Much publicity has been given to an experimental run on 17 tons of zinc ore in the Johnson electric furnace at Hartford, Connecticut, in January 1914. For some time it has been claimed that the condensation problem is solved in this furnace by the addition of incandescent carbon columns through which the zinc vapors pass before going to the condenser in order to reduce the carbon dioxide present to the monoxide. In this run the amount of blue powder re-smelted was about 20% of the spelter produced, which is a great advance over the most recent report of the work done in the electric zinc smelter at Trollhättan, where in 1912 two tons of blue powder was re-smelted with each ton of ore charged. The results of the trial run of Johnson indicate that he has made considerable progress toward a solution of the condensation problem of electric zinc smelting. While in this furnace the zinc vapors pass through a hot column of carbon before condensation, for the purpose of reducing the carbon dioxide present, it is probable that the good results obtained are largely due to a proper manipulation of the furnace so as to prevent formation of any more carbon dioxide gas than can be helped. As the charge is preheated outside of the furnace, this reduces the time it is in the furnace before losing its zinc. In this way carbon dioxide formation is prevented to a considerable extent. Also if the temperature of the furnace is controlled carefully, it is feasible to decrease the possibility of carbon dioxide formation by not permitting it to smelt so rapidly. If the speed of smelting can be kept down, opportunity is given for the carbon of the charge to reduce some of the carbon dioxide formed in smelting. With electrodes designed to be somewhat larger than actually required for carrying the current load, excessive local heating where the electrode enters the charge is prevented, giving a lower speed of reduction.

The Pato dredge of the Oroville Dredging Co., Columbia, has recovered the following since August 1, 1913: to September 8, 1914, $676,763 from 1,107,490 cu. yd.; from this date to October 1, the boat did not work, as it had capsized, but from October 1 to November 24, 232,350 cu. yd. yielded $108,850.

Rubies valued at $12,000 were recovered from 67,000 'loads' (1600 lb. each) of gravel, by the Burma Ruby Corporation in November.

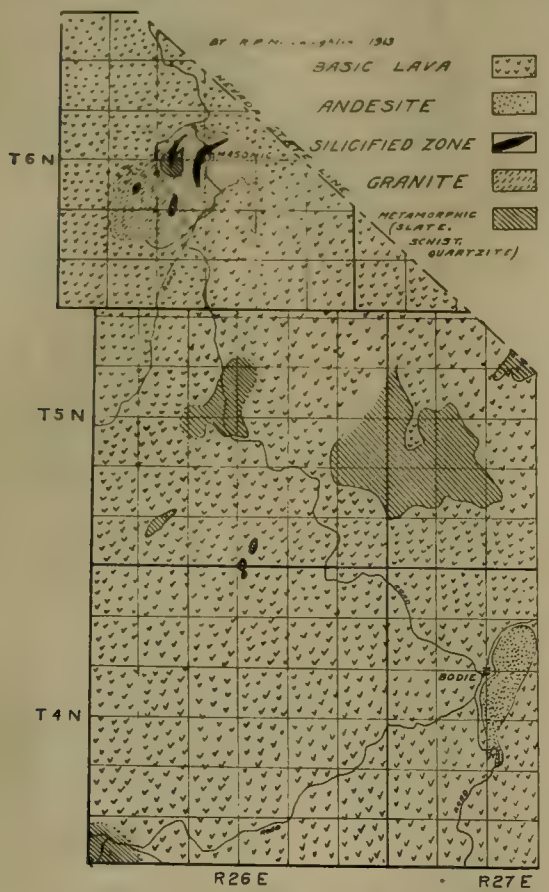
Masonic Mining District, Mono County, California

By R. P. McLAUGHLIN

The Masonic mining district is one which well illustrates the fact that our mineral resources are constantly giving us agreeable surprises. While the district is at present not very active, a description of its history and development may well follow the recent discussions on prospecting, as no extensive descriptions of it have thus far been published and the district is distinctly an asset developed by our old friend and support the prospector. Permission to publish this description is due to the courtesy of State Mineralogist, F. McN. Hamilton, as the information was gathered in course of work now being carried on by the California State Mining Bureau, which is aiming to furnish similar information upon the entire state. The illustrations are reproduced from drawings made for the Bureau.



MAP OF MONO COUNTY.

The district lies about 16 miles, by wagon road, northwest of Bodie and about two miles distant from the California-Nevada boundary line, at an elevation of about 8000 ft. It is the most recently discovered district in Mono county where any considerable amount of work has been done and ore of high grade has been mined.

Masonic and the neighborhood have been known for many years and some slight prospecting had been done, but the discovery of valuable ore was made August 1, 1902, when J. M. Bryan, Kaleb Dorsey, and J. S. Phillips made locations on what has since been called the Pittsburg-Liberty mine. They had followed numerous croppings of white ('bull') quartz veins, in the granite, with out good results and finally panned some of the dark porous croppings prominent in the neighborhood with more encouraging results. The three partners were old time miners who regularly spent a portion of their time working for wages and the remainder in prospecting.

Not until three years after the locations were made was ore in workable quantity or value found, and no considerable production was obtained until 1907 when they shipped to the Selby smelter near San Francisco a carload of ore (17 tons), which netted them $1040 per ton. This was the product of five men's work during the summer and at only a depth of 15 ft. An option was given to George Wingfield and a payment of $47,000 received. The option resulted in sinking a 100-ft. shaft and driving a 47-ft. cross-cut. However, title did not pass from the locators, due to their not consenting to alteration of terms, and they, upon taking charge of the property again, shipped ore to the amount of three carloads, the poorest of which gave them a profit of over $700 per ton. The Pittsburg-Liberty Mining Co. was formed and a 10-stamp steam-power mill was erected about a mile down the cañon.

The mine operated until 1910, the reported production being $600,000 to $700,000, and has since been idle. No large profit is said to have resulted, which is remarkable when it is considered that the maps show only about 6000 ft. of drifts and cross-cuts. Finding a mine and operating it, however, are separate and distinct problems calling for different sorts of ability and training.

Careful inspection of the workings is impossible, as the property is idle. Several veins or zones were stoped, most of them dipping at angles from 70 to 90°. The greatest depth stoped below the croppings was about 150 ft. The lower works being obstructed at the time of my examination, observations could not be made as to the geologic reason for loss of value. Assay plans show orebodies of very irregular shapes and value. Most of the value is in gold, some ore running as high as $300 per ton. From inspection of assay plans it seems probable that the average value was about $20. No machinery was used in the mine. Stopes and drifts were supported by nut pine timber from the surrounding hills. Chutes to the lower adit furnished outlet to the wagon road running to the mill. Timber is cut under permit from the U. S. Forest Service at an average price

of $1.75 per cord. Some of the most noticeable facts indicated by the mine map are: Five veins, striking N.25° W. and dipping to the east, developed upon the upper or 130-ft. level, three of them developed on the second or 172-ft. level; exposure by one cross-cut under the entire group of veins on the third or 271-ft. level; and a lower adit or 413-ft. level which cuts almost all of the mineral zone about 100 ft. south of the most productive portion. An area 300 ft. square covers most of the workings.

The east wall of the silicified zone, according to description by J. M. Bryan, is shown on the map of the 413-ft. level. North of the main adit the general dip is said to be toward the east, while on the south side the dip is westerly. Horses of granite are said to have been common in the mineralized or silicified zone.

Possibility of extension of known orebodies or other discoveries is the most important economic question relating to the district. The geologic features and positions of some of the prospecting works are shown on the accompanying map and a brief description of the geologic conditions may be interesting.

The oldest rock in the region is the metamorphic series which consists of schist, quartzite, altered slate, and similar rocks. It possibly belongs to the same series as the so-called slate extending along the eastern flank of the Sierra Nevada mountains. One of the most prominent exposures of this series is in the vicinity of Rough creek, about four miles north of Bodie, where it consists of some large croppings of chalcedonic quartzite, dark, almost black quartzite showing contorted lines either of bedding or flow under pressure. In other places, as near the state line, T. 5 N., R. 27 E., the quartzite has scarcely lost the appearance of a fine hard sandstone, with gently dipping beds and also varies to the appearance of black flint and white porcelain. Cinnabar in a 2-ft. vein of chalcedony occurs in this vicinity and some work was done many years ago.

That portion of the series near the town of Masonic consists mostly of fine grained mica schist, while that along the wagon road about six miles south of Masonic shows light colored slightly altered shale. Small areas in Sec. 34, T. 5 N., R. 26 E., are interesting on account of their isolation and small extent. Faulting is evidenced by slickensided exposures.

As seen from the above brief notes, the series is complex, probably having originally consisted largely of sediments which have been altered by heat and pressure during the upheaval of the Sierra Nevadas and the accompanying granitic intrusion.

The granite around the town of Masonic varies in different portions of the area, but is usually coarse grained, showing feldspar crystals frequently a half-inch long. It is broken by several series of joint planes. North of town their strike is northeast and southwest, dipping about 60° toward the northwest, while south of town the most prominent fractures strike nearly east and west and dip northward. Probably the entire mass has been subjected to severe strains and movements, causing some of the more prominent jointing planes. Along the southern and eastern borders of the metamorphic area, one-half mile west of Masonic, the relation of the two series is plainly seen.

That the granite is the younger is shown by its intrusion as dikes, several feet wide, for a distance as much as 50 ft. into the schist, which is generally laminated parallel to the contact line between the two formations.

The silicified zones are among the most important features shown on the map, as in them occur most, if not all, of the orebodies of the Masonic district. North of the main road through the district, in section 15, is a bold quartz or quartzite outcrop several hundred feet wide and over one hundred feet high, being one of the

Sections 15, 16, 21, and 22 T. 6 N., R. 26 E., M. D.

MASONIC MINING DISTRICT; GEOLOGY, PATENTED CLAIMS, AND PORTION OF DEVELOPMENT; FROM CALIFORNIA STATE MINING BUREAU.

most noticeable portions of the silicified areas. These zones doubtless exist in places where considerable fracturing and possibly movement has taken place in the granite country rock. The zones correspond closely with the general direction of the jointing planes in the granite. It is also suggested by some observations, notably about 200 ft. southeast from the Serita shaft, that there may have been intrusions of igneous dikes along some of the fractured areas.

In general the rock in these zones is quartz, but not in the usual vein formation. It is usually dark colored or rusty in appearance and the walls of the zone are not clearly distinguished especially upon the surface of the ground. It is made up of large quartz boulders, silicified granite, breccia, and some clay as from decomposed country rock. The ore of the district has an open or porous appearance consisting of light colored chert and coatings of chalcedonic quartz accompanying breccia of

light colored angular fragments cemented in a dark brown ground mass. Its appearance is unusual as compared with other orebodies of the neighborhood, which doubtless accounts for its comparatively recent discovery. It indicates that after quartz began to be deposited there were many disturbances in the channels opening, closing, and crushing. Irregular shaped orebodies are to be expected.

Ore Treatment and Costs at Stratton's Independence

The following data are from the report of the mill superintendent, W. H. Harrison, for the year ended June 30, 1914:

There was a total of 39 men employed at the plant, consisting of four at the ore dump, four on coarse crushing and sorting, ten on fine crushing and concentrating, ten in the cyanide department, two at the mine breaker, one on the residue dam, and eight on general repairs.

Mill results were as follows:

Details of operation.	1913-14.	1912-13.	1911-12.
Dump ore treated, tons	88,192	104,111	99,372
Mine ore treated, tons	45,683	25,999	13,019
Total	133,875	130,110	112,391
Average gold content, oz. per ton	0.1439	0.1538	0.1550
Value per ton	$2.974	$3.179	$3.204
Concentrate produced:			
First grade, tons	1,598	.....	.....
Second grade, tons	373	.....	.....
Total concentrate, tons	1,971	1,974	.....
Average gold content:			
First grade, oz. per ton	4.358	4.118	4.3425
Second grade, oz. per ton	1.848	1.847	1.3495
Gold recovered:			
In concentrate smelted, oz.	7,655	.....	.....
As bullion in mill, oz.	7,764	.....	.....
Total	15,419	.....	.....
Extraction by years:			
In concentrate, per cent	39.716	34.43	42.19
As bullion, per cent	40.283	44.05	31.44
Total recovery	80.000	78.48	73.63

Costs in 1913-14	Per ton.
Coarse crushing and sorting	$0.156288
Fine crushing, concentrating, and treating concentrate	0.504038
Cyaniding and special chemicals	0.467226
Miscellaneous expense	0.142532
Total milling charge	$1.270084
Mining dump ore	0.111041
Total	$1.381125

The gross profit was $124,760, of which $26,251 was paid to the mine department on the usual scale of treatment charges for low-grade mine ore. This left a net profit to the mill of $98,509. There were no noteworthy changes in treatment methods, the higher recovery being due to the increased tonnage of oxidized ore coming from 'A' level. This is easily cyanided. Less chemicals were used, labor cut to a minimum, and costs were therefore lowered. The plant is in splendid physical condition. The current year will see the end of mill

CONCENTRATOR ROOM IN STRATTON'S INDEPENDENCE MILL.

ing the dump, so costs will increase here, and profits will probably not be as high as previously.

Costs at the Kalgurli Mine and Mill

This property is at Kalgoorlie, Western Australia, and during the past financial year produced 127,870 tons of ore averaging $9.60 per ton. Dividends totaled $461,000.

	Cost per Ton		
Mining:		Ball-milling and conveyors	0.48
Superintendence	$0.04	Roasting furnaces	0.68
Breaking ore	0.55	Separating and settling	0.06
Timbering stopes and passes	0.04	Grinding pans	0.26
Loading and tramming	0.38	Agitating and filter-pressing	0.48
Filling stopes	0.13	Disposal of residue	0.12
Tools	0.04	Water	0.14
Sundries	0.02	Oiling	0.02
Total labor	$1.20	Amalgamation and precipitation	0.08
Total stores	0.28	Clean-up	0.02
Hoisting and drills	0.25	Sampling and assaying	0.02
Proportion of management	0.15	General treatment	0.04
Total mining	$1.88	Proportion of management	0.21
Milling:		Total milling	$2.81
Superintendence	$0.07	All costs	$4.69
Rock-crushers	0.07		
Aerial tramway	0.06		

The average residue was 78 cents per ton.

METAL OUTPUT of the Consolidated Mining & Smelting Co. of Canada from 1894 to date totals 1,462,012 oz. gold, 26,017,332 oz. silver, 333,913,214 lb. lead, and 57,890,794 lb. copper, worth $66,503,334, from the treatment of 3,925,822 tons of ore.

IRON PRODUCTION OF GERMANY naturally shows a large decrease, the output in September being 580,087 tons against 1,564,345 tons in July.

DISCUSSION

Readers of the MINING AND SCIENTIFIC PRESS *are invited to use this depar'ment for the discussion of technical and o'her matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary 'o his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.*

The Gumaos Dredge

The Editor:

Sir—I note in your issue of November 14, among the news items from the Philippine Islands, that you publish the results of the Gumacs company's dredge for August, giving the value of the clean-up at P73,284, equal to $36,642 in U. S. gold.

You also mention that the dredge worked 517 hours and handled 82,000 cu. yd. of gravel during the month—all of which is correct—only, I would like to call the attention of your readers to the fact that the percentage of the running time of this dredge is much greater than the 517 hours would indicate, due to the fact that the Company operates only six days a week, closing down on Sundays. The possible running time for the month of August would therefore be 26 days or 624 hours, instead of 31 days or 744 hours. Hence the percentage of running time is much greater than indicated in your note.

This dredge was built by my company, the New York Engineering Co., and the clean-up of $36,642 together with the large yardage handled by this dredge, certainly affords good evidence of the success of gold dredging in the Philippines when the proper equipment is selected and properly installed.

A. C. LUDLUM.

New York, December 5.

Operation of Oliver Filters

The Editor:

Sir—Supplementing Messrs. Morrison and Thomson's notes on Globe filter practice, printed in the *Press*, October 10, a few words of the experience at the Commonwealth mill at Pearce, Arizona, may be of interest.

As a preliminary let it be stated that the filter unit consists of four Oliver filters, 11.5 by 16 ft., a dry-vacuum system being used working through a receiver, from the bottom of which an elevated goose-neck connects with the vacuum-pump. A duplex vacuum-pump is used, with a rotary for use in emergencies. In the original installation, the goose-neck from the receiver to the vacuum-pump was built to allow a few feet more than the theoretical height necessary at this altitude, but sufficient air was drawn through the filters to form what might be termed an air-lift, and it was necessary to raise the goose-neck an additional 11 ft. to prevent drawing over of filtrate.

In the Commonwealth mill, the arrangement of four Dorr thickeners for counter-current replacement after agitation has caused much of the pregnant solution to be already replaced by the time that the filters are reached, so that the metal content of the filter sludge is small, and the assays of washed and unwashed residues show small loss of 'soluble values.'

The washing arrangement consists of four 1½-in. spray lines, each having nine Vermorel rotary spray tips. In the course of the regular routine, all water entering the mill circuits is added by means of these sprays. Four such spray lines, with nine sprays each, under a head of 25 lb. pressure, give 120 lb. of water per minute, which with a cake of a scant half-inch in thickness, means 120 lb. of water to 340 lb. of dry slime. A cake of one-quarter inch thickness will, of course, double the ratio of wash water to slime, but cakes of a lesser thickness indicate a fouled condition of the filtering medium, and all of the wash water is not drawn through, but runs down the filter into the sludge hopper and dilutes the sludge. The arrangement of the piping does not permit of the substitution of barren solution for wash water, in any of the spray lines. However, in this particular case, the mechanical loss of cyanide by such a substitution would be greater than the gain in the lessening of 'dissolved values.' In passing, it should be mentioned that extraction in the course of the four thickeners being nil, none is looked for during filtration.

The filters are provided with the usual side air-lifts for the circulation of the sludge from the bottom to the top of the hopper, but the foundation arrangement is such that they cannot be readily cleaned, and they are no longer in use. Agitation is secured by means of the mechanical agitator, used for a half hour twice each shift, supplemented by air jets in case the filter is stopped for any reason and the cake dropped. There are eight of these jets arranged along the side of the hopper and extending down into the sludge eight feet. These are used to break up dropped cakes, which tend to pull up and jam on the sides of the hopper, or in case the mechanical agitator does not work.

The filter canvas is scrubbed by means of five stationary brushes fastened to the traveler screw of the winding rig working on the long screw alongside of the filter, acid solution being sprayed upon the canvas from a spray nozzle and garden hose attached to an elevated tank. This, with an occasional hand scrubbing, keeps the canvases in good condition. Were it permissible, an acid treatment by spraying the acid on the

drum from a spray line and drawing it through the canvas by vacuum, would give the best wash. I understand that this is done by having a small auxiliary vacuum line connected to a separate receiver, from which it is pumped back to the spray line. It is not necessary even to drain the sludge hopper, merely draw down the sludge so that it does not touch the drum, close the filtrate vacuum line, and open the auxiliary acid line, then start the acid circulating.

Lately the practice has been adopted of washing the canvas with a fire hose with water under high pressure, the stream being directed on the discharging section of the canvas. As this section is under air pressure from within the drum, the impinging water exerts a kneading action on the canvas which flakes off much of the encrusted lime, and the air assists in forcing out matter in the pores of the fabric.

This pressure water wash has doubled the period of time between acid washes. It might be worth while, if high-pressure water was not otherwise available, to install a pump to give a high pressure to a small volume of water for washing, as the volume of water seems not so essential as the height of the pressure.

As the life of the canvas filter cover seems to have been shortened by rotting underneath the wires, due to the latter rusting, one filter drum has been wound with wire that is coated with P & B paint. This painting of the wire was done by passing the wire over a grooved wheel, the lower edge of which revolved below the surface of the paint in a shallow reservoir. This filter has not been operated long enough to determine whether or not this treatment is beneficial, yet it involves but little additional trouble and while the paint will quickly wear from the outside face of the wire, it is reasonable to expect that the inside, where it rests on the canvas, will retain its coating and lessen the rusting.

If the filter canvas is kept in good shape, the cake kicks off clean, and the discharge apron only serves to divert it into the tailing launder, but if one tries to use this discharge apron as a scraper to remove the cake, he will soon be busy. The saw-toothed edge worn on the discharge apron by the drum wires, is taken care of at the Commonwealth mill by a very simple arrangement. A bolt with a threaded nut on the end of it is substituted for the supporting pin of the discharge apron so that the apron can be shifted lengthwise every day. This, with an occasional filing keeps the edge in good condition.

FLEETING DEVICE, TO PREVENT SAW-TOOTHED EDGES ON DISCHARGE APRON.

D. W. Minter.

Pearce, Arizona, November 17.

Shall the Institute Express Opinions?

Members of the American Institute of Mining Engineers will be asked to vote at the February meeting upon important amendments to the Constitution designed to remove the existing limitations upon any expression of opinion whatever by the Institute. The matter is of first importance and we have received many letters on the subject, but have withheld publication until members should have received the official statement for and against, prepared by a special committee of the Institute. That now being available and the whole matter public, we present below two of the letters at hand and will print others next week.—Editor.]

Reasons for Adopting the Proposed Amendments

It is not generally understood by the membership of the Institute that although its 5000 members include most of the men who are in charge of the mining and metallurgical industries of the world and the organization is therefore one of the greatest dignity and strength, it is at the same time in the singular position of a giant in chains. It is tied down rigidly by constitutional restrictions which permit it to do practically nothing beyond talking and publishing. These restrictions date back to the origin of the Institute when it was feared that special interests might utilize it for their own ends. The Institute and its organization has long since developed to such a point that nothing of this kind is possible now and there is no reason for retaining the restrictions.

It is therefore proposed to remove them and to make it possible for the Institute hereafter to act for its own welfare in any way which it may deem wise. The issue presented to members by this circular therefore is whether or not they wish the Institute to have freedom of action. The restrictions which it is desired to remove illustrate an evil which is found in some form in most constitutions and which is so subtle that it has doubtless crept into ours without any recognition of its true nature by the framers of the constitution.

This is the attempt to tie the hands of our successors in order to make sure that they will always act in accordance with our own views. It is caused by a weakness which is common to us all, the feeling that there will never be any wisdom in the future quite equal to our own and that we should, therefore, endeavor to think of everything that could happen in the future and prescribe to the people who are to run affairs then what they ought or ought not to do in each case. It is not believed that

any set of men are competent to so dictate the policies or the acts of their successors, nor is there any reason why this should be permitted.

The only proper function of a constitution in an Institute like ours is that of formulating the organization and its mode of procedure, and it should stop there. Once organized the Institute is quite competent to convert the will of its members into action at any time and upon any subject. Whether some act in the future will be wise or foolish is the business of the Institute members and officials at that particular date and it is certain that no one else will be in any better position for the exercise of good judgment. If 5000 members, with a complete and modern organization for formulating their will and expressing it in action, cannot be trusted to know what is for their own good at any time, then organization becomes an absurdity.

In short, whenever this Institute wants to do anything it should be free to do it. At present it is tied down in an absurd way by the aforesaid restrictions which limit its activities to social intercourse and professional papers. These narrow limits prevent any development of the general feeling which now prevails that the time has come for the Institute to do something more in this world than mere talk.

The only valid objection which could be raised against freedom of action is that at some time something might be done which in our present opinion might not be wise, and it is easy to conjure up an endless list of such bugaboos. The Institute might take sides upon the tariff question or the European war, upon religion, socialism, or some similar thing. As a matter of fact, common sense will always restrict action to suitable fields, and no board of directors would venture upon any new policy without being well assured either by its general knowledge or a referendum that it represented the will of the majority. To do otherwise would be to commit official suicide. As in any organization, the minority must be overruled, but in the professional spirit which pervades the Institute, good judgment will naturally refrain from policies which are so extreme in any direction as to cause a serious loss of membership. In any case there is no adequate reason why 5000 intelligent men should tie their own hands. The Institute ought to have complete freedom of action.

EDMUND B. KIRBY.

REASONS AGAINST ADOPTING THE PROPOSED AMENDMENTS

The function that the Institute was designed to fill is to offer a field where ideas falling within its province may be placed to the test of examination and discussion. It has admirably filled that function, and because of its success it has been suggested that to its original function of examining and discussing ideas shall be added the function of deciding upon and advocating such ideas or schemes as meet its approval.

The Institute, as at present organized, is specifically prohibited from so deciding upon or advocating any controversial matter. The Institute, as at present organized, cannot take sides. The proposed changes in the Constitution would do away with this prohibition and allow the directors practically unlimited scope to commit the Institute to take sides on any question.

The first effect of the removal of this prohibition will be the earnest, continued, and subtle solicitation of the directors to throw the influence of the Institute on the side of the financial or political interests of a certain number of members, who naturally desire to get all the available support to their propaganda. While I am heartily in favor of having the interests of the mining industry adequately presented before the country and Congress, the Institute does not seem the best means for making this presentation. It has no means for quickly and accurately ascertaining the wishes of its members who, being of many nationalities, have naturally and inevitably clashing interests. It would be unjust to decide, merely by the vote of the directors, a question which vitally affects even a small integral minority of the members.

I have seen no means suggested by which the questions that will be submitted to the Board of Directors can be classified so as to determine certainly and with accuracy whether they may or may not be decided by the board. None of the schemes so far suggested for ascertaining the wishes of the members, or for weighing the strength of the opposition to any project, seems competent to attain with speed and certainty the desired result.

While undoubtedly a certain amount of chafing against restrictions imposed by the Constitution has taken place, I do not think that the Institute has really suffered. I feel sure that if the restrictions were entirely removed and the proposed unlimited latitude allowed directors, they would be the first to rebel at the greatly increased responsibilities they would have to assume, the increased amount of time they would have to give the affairs of the Institute, not only to promote ideas they were interested in, but to prevent the adoption of schemes they thought harmful.

The proposed entire removal of restriction on the taking of sides, seems to me unwise. I have heard no definition of any new limitation that is sufficiently helpful to warrant a change in the Constitution. Without some limitation, I feel that the probabilities are great that sides may be taken on some question that will not add to the prestige of the Institute or aid its usefulness, and I am therefore not in favor of the proposed changes to the Constitution as they now stand.

SIDNEY J. JENNINGS.

FRENCH iron mines and mills at Longwy and Bruges have been placed under management of the German civil authorities. The significance of this fact will be understood when it is remembered that the district furnishes approximately 85% of the entire French iron ore production.—*Weekly Report*, American Association Commerce & Trade, Berlin.

CONCENTRATES

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

TUBE-MILL crushing capacity at the Consolidated Gold Fields plants on the Rand has been increased by means of a scoop discharge at the outlet end, which lowers the level of the pulp in the mill.

SHAFT-SINKING at the Nevada Wonder mine, Nevada, cost from $30.80 to $38.53 per foot in the past financial year of the Company. These costs are for two and three-compartment shafts respectively.

AN 8-INCH PIPE-LINE is said to be capable of delivering 30,000 bbl. of California oil per day. This is probably with light oils heated considerably, but is ordinarily in excess of the possibilities.

APPROPRIATIONS for the U. S. Geological Survey for a systematic study of the water resources of the country have totaled $12,500 to $200,000 during the past 18 years. From 1903 to 1906 it was $200,000 per year, and since 1911, $150,000.

LAMPBLACK RESIDUE from the manufacture of gas from crude oil makes a useful fuel when briquetted. It needs no binder. Analyses show the following composition: moisture, 3.04%; volatile matter, 27.32%; fixed carbon, 69.06%; ash, 0.58%; and heat value, 15,105 B.t.u. per pound. The latter is about 1000 B.t.u. more than the best anthracite coal.

A VERTICAL TRIPLE-EXPANSION WATER PUMP, with a capacity of 30,000,000 gal. per day, of Allis-Chalmers make, was recently installed at the Broadway pumping station of the Toledo Water Works, Ohio. It is far more efficient than the old pumps. Insulation of the steam cylinders and pipes is by Johns-Manville magnesia covering. The pump cost $83,000.

ADVANTAGES have been claimed from the storage of coal in water. In the annual report of Admiral R. S. Griffin, chief of the Bureau of Engineers of the Navy Engineers, he says the Bureau has not yet been able to determine the advantage to be derived from the storage of coal under water, although tests have been going on for three years at New London without so far developing any marked difference in value between coal in the open, under cover, and under water.

STATES which have taken legislative action in the mine-rescue and first-aid movement are as follows: Illinois, Oklahoma, Nevada, Colorado, Tennessee, Ohio, Kentucky, and New Mexico, according to J. W. Paul of the U. S. Bureau of Mines. Mention only is made of the states which have taken some action in promoting rescue work and training. Some of the states named have appropriated funds for the purchase of breathing apparatus only; some have required the mine operators to procure a certain number of sets of such apparatus, some have authorized co-operative training; and others have provided stations, cars, and a permanent organization for the conduct of the instruction and training of miners in modern equipment and methods.

THALLIUM is a rare metal with a specific gravity of 11.81 to 11.91, and a melting point of 303°. It occurs in certain pyrites and in mineral waters. Physically and mechanically it is like lead, but chemically it also resembles the alkali metals in many respects. It is so soft that it can be cut with the finger nail. A freshly cut surface is lustrous, but rapidly becomes dull. The metal volatilizes a little above the melting point, and when heated before a blowpipe gives a reddish vapor having a peculiar smell. Hydrochloric acid attacks thallium slowly, while other acids dissolve it rapidly. The metal is generally extracted from the flue dust of furnaces in which pyrite containing the element is burned. This dust is treated with dilute sulphuric acid, and the thallium precipitated in a crystalline form by means of zinc. The chief use of the metal is in the manufacture of optical glass of high refractive power. Thallium is worth about $11 per pound.

LIME exhibits some peculiar chemical reactions. It consists of 5 parts of calcium and 2 parts of oxygen, having the formula CaO. Owing to its chemical activity, it is not found native, but mostly as the carbonate $CaCO_3$. If this be heated, the following reaction takes place:

$$CaCO_3 = CaO + CO_2$$

If the lime produced is exposed to the air, it absorbs moisture, forming calcium hydroxide. This absorbs carbon dioxide from the air, resulting in calcium carbonate and water. Therefore, if exposed to the air, lime will gradually revert to a substance having the same chemical composition as that from which it was derived. Reactions are as follows:

$$CaO + H_2O = Ca(OH)_2$$
$$Ca(OH)_2 + CO_2 = CaCO_3 + H_2O$$

These reactions form the basis for manufacture of lime products and its various uses. The chemical uses are numerous in the agricultural, bleaching, caustic alkali, chemical gas, glass, grain milling, oil, fat and soap, ore treatment, paint and varnish, paper, preserving, sanitation, smelting, sugar, tanning, and water softening and purifying industries.

MINING IN THE FAR NORTH*

Placer Mining in the Fairbanks District—Continued

By EMIL EDWARD HURJA

Placer mining on Fairbanks creeks has undergone considerable change from the earlier days of the creek, when hundreds of thousands were taken out with a few men working in a single season. There are a number of large concerns which are making a business of mining, systematizing the work, and cutting down expenses wherever possible, in order to permit the low-grade ground to be worked as economically as possible.

Two plants are at work on No. 1 Below, creek claim, one of Rogge, Grill & Griffin and the other of Jacobson & Pearson. The operations of the latter plant are at the mouth of Alder creek, on ground owned by L. C. Hess. A slip scraper was used early in the season, but was replaced by a bottomless Bagley scraper later. A 40-hp. boiler and a 6¼ by 10 double-drum American hoist comprise the equipment. It was planned to work 25,000 sq. ft. of bedrock during the summer season. Ten men were employed. The ground prospected $1.25 per square foot. The Rogge, Grill & Griffin plant was on ground owned by Meehan & Larson. Fifteen men were employed. A slip scraper, operated by a 50-hp. plant was used to work the 'pay' from the bottom of the cut. The ground is 20 ft. deep. A second cut was started late in the summer.

Above Discovery claim, Lappi & Holkie worked on No. 2 Above. They had a 25-hp. boiler and had six men working. The depth to bedrock was 22 ft. Fred Parker's open-cut work on No. 3 Above is the most important work in the creek, so far as size of plant and output is concerned. The summers' output was nearly 50,000 sq. ft. of bedrock, and the plans for next year provided for an increased output in 1915. A 3½-ft. Bagley scraper was operated by a 7 by 10 American three-drum hoist. The boiler capacity of the plant was 50-hp. Ten men worked each shift during the summer. Pole riffles and one box of Hungarian riffles served to catch the gold. Two plants worked on No. 4 Above, one, a small one owned by Charles Felton and the other by Frank Mueller. On 16 Above, Charles Schafer operated a small placer plant. Huddleston Brothers and Henry Pate worked on 16 Above, near the head of Fairbanks creek, driving into the hill for a bench run of 'pay.' On No. 8 Above, creek claim, the Alaska Exploration Co. is conducting dredging operations. The Company was financed by English capitalists and the work was in charge of G. Aarons during the past season. Because of the age of the dredge, numerous breakdowns greatly reduced the operating length of the season. The dredge has 3½-cu. ft. buckets in a close-connected line and a 40-ft. ladder. Steam is the motive power. Wood is used for fuel. The depth of the ground is from 10 to 12 ft. Due to an error in judgment, the dredge during 1912 and part of 1913 worked through a pile of tailing made by itself in order to work back to virgin ground that had been overlooked. The operation during the present season was reported to be successful. A Keystone No. 3 drill was used on the Company's holdings on upper Fairbanks creek during the summer in prospecting work.

The productive area of the Goldstream basin extends from the Goldstream flats, two miles or more below the town of Fox, upstream to the confluence of Pedro and Gilmore creeks, and both of those streams to the near headwaters. The Engineer Creek valley is producing a little. It is tributary to lower Goldstream. It was on Pedro creek that the first discovery of gold in the Fairbanks district was made, the creek getting its name from the discoverer.

Co.,' November 14; 'The Klondike, the Treadgold Placers, and Outlying Districts,' November 28; 'The Upper Yukon: Circle City, Eagle, and Woodchopper,' December 5; 'Placer Mining in the Fairbanks District,' December 19.—EDITOR.]

OPEN-CUT WORK ON NO. 8, BELOW, PEDRO CREEK, FAIRBANKS DISTRICT.

Aside from a little unimportant mining on Twin creek the placer mining activity in the Pedro valley may be said to start at the mouth of Twin creek. There Gustafson & Carlson are operating an open-cut plant. Charles Gius is mining with another big open-cut plant below them, below him is Julius Gius and then in order going downstream, Mudge & Co., Morgan & Co., Harry Atwood, C. A. DeRuchia, and McPike & Gilmore, all on Pedro creek. Then on Goldstream, Koch, Kerrigan & Cullinane operate on No. 2 Below, F. C. Bleeker on No. 5 Below, and Henry Wagner on No. 6 Below, each have open cutting operations in full swing.

All of the Pedro creek open-cutting plants are of the same type, double or triple-drum hoisting engines controlling buttomless scrapers with cable through blocks set at different points along the bank of the cut, scraping directly into the boxes. Mudge & Co., Gustafson & Carlson, and Mogan & Co. started their operations last season, and were fortunate in having good water conditions to help them along in the initial stages of the work. Atwood has been operating on Pedro creek for a number of years, in fact, he was one of the first men to stake on the creek. He was a member of the Parnette trading expedition which established Fairbanks in 1902.

The DeRuchia outfit's work on No. 8 Below, Pedro, for 1914 provided for cleaning up 75,000 sq. ft. of bedrock. A wheel scraper of 16-cu. ft. capacity was drawn 46 ft. up an incline to a dump-box 27 ft. above the ground by an American double-drum hoist. Two 35-hp. boilers furnished power for the work. A bedrock drain was cut before the work was attempted. The dump-box has block riffles followed by Hungarian riffles. The plant operated night and day, with 20 men employed.

On No. 9 and No. 10 Below, Pedro, James McPike, and Thomas Gilmore have a battery of boilers aggregating 90 hp. operating a 50-hp. American triple-drum hoist in an open-cut that promises to yield for four years more. One Bagley No. 3 and one No. 4 scraper are used. The dirt from the cut is scraped directly into the dump-box, which has a length of 80 ft., a width of four feet, and is underlaid with 5 and 6-in. block riffles. The sluice-boxes have a width of 20 in. Iron-shod pole riffles are used in the string. The work last summer cleaned up two blocks of ground, aggregating over 70,000 sq. ft. A big block was opened up for operations in the spring of 1915 as soon as water starts to run.

Koch, Kerrigan & Cullinane are operating on No. 2 Below, Goldstream, with a 70-hp. plant. An American hoist, $8\frac{1}{4}$ by 10, operates a yard slip scraper. After the ground, which is 17 ft. from surface to bedrock, is stripped of 'muck' and waste, the last six feet is scraped into the sluice-boxes. Part of the 'pay' occurs in bedrock. The dump-box is 60 ft. long, 40 in. wide, and contains block riffles. Hungarian riffles are used in the sluice-boxes.

On No. 5, Goldstream, creek and right limit bench claims, F. C. Bleeker operates two plants about 1500 ft. apart. One has a 70-hp. locomotive type boiler, with an $8\frac{1}{4}$ by 10-in. American hoist; the other has a 90-hp. boiler with a similar hoisting engine. The first plant had as its season's work, a block of 80,000 sq. ft. of bedrock to scrape. The other had a block of 55,000 sq. ft. The average depth of the ground is 18 ft., with a minimum of 12 and a maximum of 30 ft. The 'muck' ranges from 6 to 15 ft. deep, with an average of 9 ft. Some of the 'muck' is ground-sluiced off, but because of the absence of perceptible grade, most of it has to be scraped. Water is pumped 15 ft. to the flumeway by two pumps, a Crow and a Morris. Six hundred feet of flume carries the water to the dump-box. Two slip scrapers are used, each with a capacity of 30 cu. ft. Two and one-half feet of bedrock is taken up. The dump-box is 54 ft. long. Iron-shod pole riffles are used in the upper end of the dump-box, with perforated metal riffles and cocoa matting below. The cost of operation is 25c. per square foot of ground worked. Henry Wagner has one scraper of the Bagley type at work on No. 6.

TYPICAL PLACER PLANT, FAIRBANKS DISTRICT

On No. 8, Goldstream, Martin & Co. had 12 men at work in drifts. The depth to bedrock is 28 ft. A 50-hp. plant furnishes power. Visaco & Co. have a crew of ten men working on No. 9. The ground is 35 ft. deep. Vicaire & Co., with a 30-hp. plant and 10 men employed, have started driving operations on No. 10. The ground is 40 ft. deep. They expect to take out a dump during the winter. Genoss & Co., on No. 11 Goldstream, have two 25-hp. boilers to furnish power for hoisting. Ten men are employed. Mogstad & Co. have a crew at work on No. 12. Casalegno & Dunn finished their work on No. 14 early in the fall. They had a crew of 14 men working for several months during the summer sluicing season.

Peterson & Co. are preparing to open up a new block of ground on No. 17, Goldstream, a claim which probably has produced more gold than any other in Goldstream and more than many others in the district. It formerly was owned by L. L. James, now of San Francisco. The depth to bedrock on the upper end of the claim is 95 feet.

James Russell and Huddleston Brothers are working on 22, Goldstream, taking out a little gold. The depth to bedrock is 50 ft. On the Perlenda ground on 23, Goldstream, Brown & Co., and Leaf & Carroll are working. They sluiced a little during the summer. E. A. Williams, on the lower end of the Owl Association claim on Engineer creek, had a crew of 30 men working during the summer. He has a 70-hp. plant on the ground, which is of low-grade and has to be worked on a large scale to be profitable. The ground is 60 ft. deep. Herbert Williams is prospecting on the upper end of the Owl Association. O. W. Fisher also is prospecting on upper Engineer. DeWree & Co., at the mouth of Blanche gulch, an Engineer tributary, had 10 men working for a time during the summer, using a 25-hp. plant in the work.

The Ester Creek district continues to be profitable, although the richer placers have been worked out. The rich tributaries of Ready Bullion and Eva creeks are still yielding some gold, although the richer parts of the streaks have been taken out long ago. Prospecting is expected to demonstrate unworked parts of the streaks.

On Eva creek, Charles Lind & Co. are prospecting the Minnesota Association claim, owned by Harry Wallace. Drill work done there two years ago showed up good ground, which was not worked because of the presence of 'live' water. Charles Pyne & Co. are working on the upper end of the Happy Home Association claim, sinking a prospect shaft. The Happy Home has produced between $400,000 and $425,000. McIntosh & Co. have a small crew at work on the Daly bench, taking out side 'pay.'

The Mihalcik bench yielded between $60,000 and $70,000 during the past year on Ready Bullion creek, tributary to Ester creek. There is no more work in progress on Ready Bullion, with the exception of desultory prospecting for a side streak on some of the worked-out claims.

Tom Isaacson & Co. are working on No. 3 Above, with a small crew of men. A new side streak was recently found, and a 30-hp. plant was erected. The depth of the ground is 80 ft. The season's probable output of the claim was 10,000 sq. ft. of bedrock. Olson & Sullivan, working on the upper end of No. 1 Above, erected a battery of boilers, one 40-hp. and the other 35-hp. and started to open up for the winter. They expect to open 60,000 sq. ft. of bedrock in readiness for the beginning of sluicing next spring. Thirty-five men are employed. On No. 1 Above, George Rey is prospecting the Haskell claim. Sandstrum & Co. have a lay on the upper end of No. 1 Above and recently erected a 30-hp. plant. They have a crew of six men working. Keith & Co. have a 25-hp. plant on No. 3 Above, with six men employed. On Gold Hill, the left limit bench of Cripple creek, three plants worked almost continuously during the summer. The Gold Hill Mining Co. employed 15 men until the first of August. Beck & Co. had 12 men working until the end of the sluicing season. Alm Brothers employed eight men for a greater part of the summer. On Happy creek there is one plant at work.

Little Eldorado is a tributary to the Chatanika, a few miles below the mouth of Cleary creek. Several small plants worked on the upper end of the creek during the summer, but their total production probably did not amount to more than $10,000. Jess Noble, on No. 5 Above, first tier, right limit, bench, was drowned out early in the summer and was forced to sink another shaft. The depth to bedrock is 110 ft. Eight men were employed in the fall. The 'pay' is said to be rich. Howser & Co., working on No. 2 Above, recently erected a 30-hp. plant after finding 'pay' and made considerable profit during the summer. Erickson & Anderson, on No. 2 Below, Little Eldorado, had a 30-hp. plant on their ground, which is 100 ft. deep and contains a pay-streak 120 ft. wide. The gold is in the gravel for four feet above bedrock. Sixteen men were employed through the summer. Whaley & Co. had six men working during the summer on No. 6, first tier bench, right limit, where the ground is 150 ft. deep.

On the Eldorado Association, opposite No. 8 on the first tier of left limit benches, Hearn & Rundlund have a 40-hp. plant and have 18 men working. The depth of the ground is 150 ft. Hess & Erickson, on No. 9 Below, had 20 men working during the summer. They took out 50,000 sq. ft. of bedrock. W. T. Burns, who recently was interested in the Chatham Mining Co. on Chatham creek, has started to prospect his holdings on the Oregon Association at the mouth of Little Eldorado.

On Vault creek, most of the mining was being done at the mouth of the stream, where it emptied into the Chatanika. The Cook interests operated on the Sarah Association near the mouth of Vault for most of the summer. The plant is 50-hp., with a 5½ by 8-in. American hoist. The ground is 200 ft. deep, of which 100 ft. is 'muck.' The 'pay' is in gravel almost entirely, a distance of 2½ ft. above bedrock. The pay-streak is 80 ft. wide. Ten men worked during the summer, after the blocking out operations had been completed during the spring. Water is obtained by gravity through ditching.

The bulk of Dome creek's placer mining this year was done near the mouth of the creek. The richer placers farther upstream which were the cause of so much strife and squabble in Fairbanks' early life, have been depleted. Quartz mining is taking the place of the placer mining at the head of the creek

Chester Johnson had 14 men working most of the summer on lower Dome. Victor Kleinschmidt had a crew of 18 men working during the season on the upper end of the Niggerhead Association claim, in which he holds an interest. Peter Letender worked on the Shakespeare claim for a short time during the summer, but closed down about August 1. Gust Dourell and partners are prospecting on the Day Dawn claim, in the flats of the Chatanika.

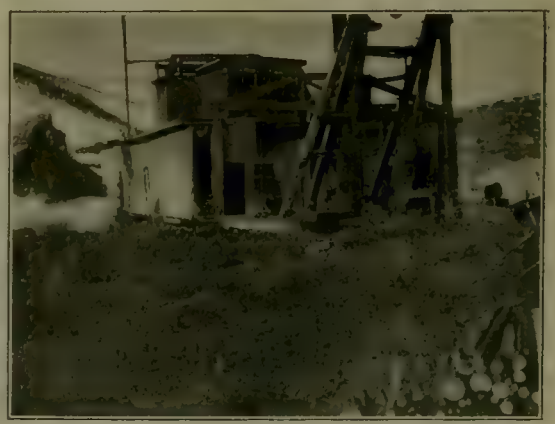
S. P. Magnusson operated the lower lay on the Niggerhead claim all summer long. The boiler capacity of his plant was 110 hp., with a single drum 7 by 10 American hoist. A 120-light dynamo plant also is included. The depth of the ground is 170 ft., 18 ft. of it 'muck.' Four feet of dirt was taken out as 'pay,' almost all of it in bedrock. The streak is 276 ft. wide. Magnusson has cleaned up 550 ft. of the streak up and downstream. Thirty-eight men are employed. The ground averages 90c. per square foot.

The gold placer area known to miners as the Tenderfoot district is about 60 miles southeast of Fairbanks and embraces the watersheds of several small streams flowing into the Tanana from the north. Richardson, on the Tanana river, is the supply centre for the district. Gold was first found there in 1905 and up to 1909 the gold production was about $400,000 yearly. Since that time it has been decreasing steadily. The Tenderfoot gold assays $12.25 per ounce, lower than any other gold in the interior of Alaska.

Lawrence Albrecht is working on No. 16 Tenderfoot creek. The streak, where he is mining, has a width of 50 ft. The depth to bedrock is 170 ft. Between $50,000 and $70,000 will be taken out by him this year. Thirty-five men are working. E. Hearn has 12 men working on No. 5 and No. 6 Tenderfoot, where the ground is 90 ft. deep. He is doing well. Lenot, Chinquist & Rearden are employing ten men on No. 4, Tenderfoot. Melvin, Pohl & L'Kievicz are open-cutting on Democrat Pup, a tributary of Banner creek. Jacob Samuelson is working at the head of Democrat Pup. He made his first clean-up recently, taking out from $800 to $1000 by ground-sluicing.

Open-cut work will be conducted on Portage creek, a tributary to the Little Delta river, 100 miles from Fairbanks, next year. The mining work on Portage consists largely of ditch building and preparatory work on unwatering ground for open-cutting. Val Diebold, J. A. Gustafson, and Emil Johnson are interested in a group of five claims, and they expect to do their first work on No. 1 Below. The ground is 10 ft. deep, of which two feet is 'muck.' A 200-ft. bedrock drain is under way, which will make it possible to work the ground. The ground was thoroughly prospected last winter. Kelly & McDermott have completed a 4½-mile ditch which will supply them with water for ground-sluicing operations on Discovery claim.

Placer mining is being carried on in many other parts of the district tributary to Fairbanks. Miners are working in the Salchaket, Big Chena, Kantishna, Nenana, Totalaniska, Tolovana, and other areas in the Fairbanks region. The Kantishna is the only district of these which has a steady production.



DREDGE ON FAIRBANKS CREEK.

MINERAL PRODUCTION IN 1914

Preliminary figures of production for a number of the states and for Ontario are given below. Additional figures will be printed from week to week as they become available.

U. S. Geological Survey Estimates

Wyoming's Small Metal Yield

With final figures for 11 months and an estimate for December, the total for last year was $2850 gold, 100 oz. silver, and 17,000 lb. copper, which is a decrease for all metals compared with 1913. Considerable development and construction work was done in the Atlantic City district.

South Dakota Gold and Silver Output

The production of gold, according to preliminary estimates, was $7,270,000, compared with $7,319,294 in 1913, and that of silver was approximately 174,000 oz., compared with 172,702 oz. in 1913. A nominal quantity of lead was produced. From 1876 to the end of 1914 South Dakota has produced $185,224,000 in gold and 5,830,000 oz. of silver. The mines of the various districts have been covered in the *Press* by our regular correspondent.

Metal Output of New Mexico

The output of New Mexican mines for 11 months of 1914, with an estimate for December, indicate a yield of $1,172,000 gold, 1,720,000 oz. silver, 1,340,000 lb. lead, 65,600,000 lb. copper, and 18,300,000 lb. zinc (in terms of spelter and zinc in zinc oxide). These figures show increases of $290,000 gold, 90,000 oz. silver, 9,300,000 lb. copper, and 1,800,000 lb. zinc, and a decrease of 2,600,000 lb. lead. Despite lower prices for metals, the total value was $12,070,000 in 1914, against $11,694,002 in 1913, an increase of $376,000.

Texas' Metal Production

The output of Texas mines for eleven months of 1914 with an estimate for December, according to preliminary figures compiled by Charles W. Henderson, amounted to $9302 gold, 581,000 oz. silver, 190,000 lb. lead, 30,000 lb. copper, and 190,000 lb. zinc. These figures show a considerable increase for gold and silver, a large decrease for zinc, and smaller decreases for copper and lead. The greater part of the output of silver came from the Presidio mine, in the Shafter district. Some silver and copper was produced at Van Horn, Culberson county, and some lead and zinc in the Sierra Blanca district, El Paso county.

Metal Production of Colorado

The output for 11 months, with an estimate for December, indicates a yield of $19,860,000 gold, 8,742,000 oz. silver, 75,550,000 lb. lead, 6,677,000 lb. copper, and 96,000,000 lb. zinc (in terms of spelter and zinc in zinc oxide), with a total value of $33,300,000, compared with $18,146,916 gold, 9,325,255 oz. silver, 87,897,773 lb. lead, 7,227,826 lb. copper, and 119,346,429 lb. zinc, with a total value of $35,450,585, in 1913.

In addition to the decrease in quantities of silver and the base metals, the falling off in average value for these metals caused a decrease in value of $833,000 for silver, $921,000 for lead, and $1,890,000 for zinc.

The tonnage treated by the Globe, Leadville, Pueblo, and Salida smelters was approximately the same as in 1913. Copper ore from Rico and copper matte from Ouray were shipped to plants in Utah. Cyanide precipitate and copper ore were shipped to Omaha. The copper-matting plant at Ouray was operated steadily during the year, and a 200-ton increase was made in its capacity, construction work being completed by the end of the year 1914. The tonnage treated at the United States Zinc Co.'s magnetic plant and smelter at Pueblo was less than in 1913.

Mining in Alaska in 1914

Complete statistics of the mineral production of the territory can not be collected within less than four or five months after the close of the year, but meanwhile it appears advisable to give prompt publication to preliminary estimates, which are believed to vary not over 5% from the actual figures, according to Alfred H. Brooks, who has charge of this compilation.

It is estimated that the value of the total mineral output in 1914 is $19,248,000, compared with $19,416,000 for 1913. The preliminary figures on gold output show $15,900,000, against $16,626,813. Silver was $191,000 and $218,988, respectively. Though the low price of copper since midsummer greatly curtailed the output of that metal, about 20,850,000 lb., valued at about $2,872,000, was produced in 1914, against 21,659,958 lb., worth $3,357,293 in 1913. The output of the other minerals, including tin, marble, gypsum, quicksilver, coal, and petroleum, in 1914 had a value of about $285,000, compared with $272,242 for 1913.

Had it not been for the depression in the copper market, the value of Alaska's mineral product would have been considerably greater in 1914 than in 1913. The gold-mining industry of the territory as a whole was prosperous during the year, as is made directly evident by the figures on output, but a more important item of progress is the extensive dead work accomplished on large plants that have not yet reached a productive stage. No progress was made in coal mining, there being in 1914 only one small productive mine in the territory, and that in one of the lignite fields. It is expected that the new law providing for leasing of coal lands in Alaska will lead to the exploitation of the fields containing high-grade coal. The tin, gypsum, marble, and petroleum mining industries of Alaska had a successful year.

The certainty of railway connection with the Yukon basin has greatly stimulated both prospecting and mining development. There was a noticeable increase in investigation of large mining enterprises in 1914 compared with previous years. This was due solely to the expectation of cheaper transportation.

The data on hand indicate that the value of the placer gold produced in 1914 was about $10,700,000, or practically the same as that of 1913, which was $10,680,000. The distribution of this output is, however, not the same in the two years. Some increases in the output of the Ruby, Seward Peninsula, Iditarod, and Hot Springs districts were made, but on the other hand, there was a marked decline in the placer-gold output from Fairbanks and lesser decreases in some of the smaller camps. The abundant rainfall which occurred in most of the Yukon and Seward Peninsula districts during the mining season of 1914 greatly favored placer operations.

The Chisana district is the only new placer camp developed in 1914. Promising discoveries are reported in the Healy River region of the middle Tanana, and also a find of placer gold in the upper Tolovana basin, between Fairbanks and Rampart.

About 44 gold dredges were operated in Alaska for the whole or part of the open season of 1914. Preliminary estimates show that they produced gold worth between $2,050,000 and $2,300,000. In 1913, 39 dredges were operated, recovering $2,200,000. The decreased output per dredge in 1914 is accounted for by the facts that in 1913 several of them were working in rich ground, and that several of the new boats were not completed in time to operate for more than a

brief period in 1914. A further handicap this year was the fact that the dredging season at Nome opened later than usual. In addition to the 44 dredges operated, there were about half a dozen under construction.

About 25 gold-lode mines were operated in 1914, and produced gold valued at about $5,100,000. In 1913, 30 mines produced $4,854,813. The decrease in the number of mines is due to the fact that several which were operated in the Fairbanks district in 1913 were idle in 1914. Juneau is and will continue to be by far the most important Alaska lode district. Important progress was made during the year in the Willow Creek district. The Port Wells district was added to the gold-lode producers.

Developments made up to midsummer gave promise that 1914 would be the most profitable year in the history of Alaska copper mining. The financial stringency and collapse of the copper market that followed the European war not only closed down some of the producing mines, but also put a stop to some very important developments. Up to about the first of August seven copper mines were in operation, but at the close of the year only three were still working. Had it not been for the war, at least nine copper mines would have been ready to ship ore before the end of the year. Probably the most important events of the year to the copper industry of Alaska were the reopening of the Mamie mine, in the Ketchikan district; the installation of a shipping plant and the opening of the Midas mine, near Valdez; and the completion of aerial trams at the Jumbo and Mother Lode mines, in the Chitina district.

The report then covers the various districts in detail. These have also been dealt with in recent issues of the *Press* in the articles by Emil Edward Hurja.

Ontario Dividends for the Year

Dividends paid by Cobalt, Porcupine, and other mining companies in 1914 were as follows, according to *The Daily Nugget*:

Company.	Total 1914	Per cent.	Total amount.
Beaver	.....	20½	$ 410,000
Buffalo	280,000	284	2,807,000
City of Cobalt	.....	23	139,321
Cobalt Central	.....	4	192,845
Cobalt Silver Queen	.....	21	315,000
Coniagas	1,320,000	181	7,240,000
Crown Reserve	424,479	337	5,960,858
Cobalt Townsite	200,000	110	1,042,260
Casey-Cobalt	93,750	...	203,249
Cobalt Lake	150,000	15½	465,090
Caribou-Cobalt	50,000	7½	75,000
Foster	.....	5	45,774
Kerr Lake	600,000	184	5,520,000
La Rose	899,176	69	4,974,998
McKinley-Darragh	472,015	193	4,337,028
Nipissing	1,350,000	204	12,240,000
Mining Corp. of Canada	259,375	12½	259,375
Right of Way	16,850	78	543,754
Peterson Lake	129,096	5¼	129,096
Seneca-Superior	335,218	135	645,993
T. & H. B.	69,849	25,000	1,940,250
Temiskaming	.....	56	1,384,156
Trethewey	50,000	108	1,061,999
Wettlaufer	.....	45	637,465
Hollinger	1,170,000	87	2,610,000
Porcupine Crown	180,000	9	180,000
La Rose shared privately prior to May 1908	.....	...	1,204,862
Private corporations (est.)	300,000	...	3,800,000
	$8,349,808		$60,364,473

The silver market affected operations to some extent.

Utah Mines and Dividends

In reviewing the past year's mining industry of the state, the *Deseret Evening News*, of Salt Lake City, makes the following comments: Dividends totaled $6,996,118, against $7,678,516 in 1913, as follows:

	Dividends in 1914.	Dividends in 1913.	Total to date.
Bingham-New Haven	$ 68,607	$ 45,728	$ 548,856
Buffalo Con.	2,346	.....	2,346
Centennial Eureka	150,000	300,000	1,050,000
Chief Consolidated	87,645	175,290	262,935
Cliff	.....	30,000	90,000
Consolidated Mercur	20,000	30,000	3,470,312
Daly-Judge	180,000	180,000	855,000
Daly West	.....	27,000	6,282,000
*Duluth & Utah	10,000	.....	6,000
Eagle & Blue Bell	178,629	178,629	357,258
Gemini	50,000	100,000	2,280,000
Gethin Le Roy	.....	7,500	7,500
Gold Chain	.....	60,000	130,000
Grand Central	75,000	75,000	1,602,750
Ingot Gold	.....	750	750
Iron Blossom	400,000	400,000	2,270,000
Mammoth	.....	20,000	2,300,000
May Day	24,000	24,000	156,000
Moscow	.....	24,528	40,880
Opohongo	.....	8,989	71,918
Silver King Coalition	.....	375,000	13,397,385
Silver King Consolidated	246,706	308,382	555,088
United States Mines, Bingham	†75,000	†100,000	.....
Utah Consolidated	600,000	450,000	9,660,000
Utah Copper	4,828,185	4,747,710	26,649,006
Yankee Consolidated	.....	10,000	192,000
Totals	$6,996,118	$7,678,516	$75,237,984

*Proceeds from sale of property. †Estimated.

The total dividends during 50 years amount to $118,818,208.

The Bingham district produced approximately 8,077,856 tons of ore yielding $1,476,315 gold, 1,978,603 oz. silver, 69,520 tons copper, 31,876 tons lead, and 1503 tons zinc, valued at $22,980,688, compared with 9,190,374 tons of ore, $1,774,815, 2,408,692 oz., 72,460 tons, 35,500 tons, and 1711 tons respectively, worth $29,008,007. The war and low metal prices are the causes of the decrease.

The Alta district in 11 months produced 14,112 tons of ore worth $221,906. The tonnage in 1913 was only 5608. With the new development in the Cardiff, the current year promises well.

The American Fork district six mines yielded 197 tons of ore.

Park City, with 21 mines, showed a decrease of 10,563 tons for 11 months of 1914, the total being 64,541, against 75,104 in 1913.

Tintic, with 41 producers, shipped 300,640 tons of ore, a decrease of about 75,000 tons.

The Ophir, Santaquin, and Beaver districts developed in a promising way.

The smelters near Salt Lake City yielded the following:

Metal.	1914.	1913.
Gold, ounces	160,863	172,711
Silver, ounces	12,821,378	13,084,835
Copper, pounds	157,162,611	161,445,962
Lead, pounds	190,245,670	166,126,790
Zinc, pounds	23,349,295	18,857,827
Arsenic, pounds	2,051,940	1,288,815
Total value	$40,258,487	$44,974,203

These values are based on the following average prices: silver, 54.69c. per oz.; copper, 13.15c.; lead, 3.82c.; zinc, 5.15c.; and arsenic, 9c. per pound.

There were 198 producing mines in the state yielding 8,618,832 tons of ore, against 10,202,566 tons in 1913.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

NEW YORK

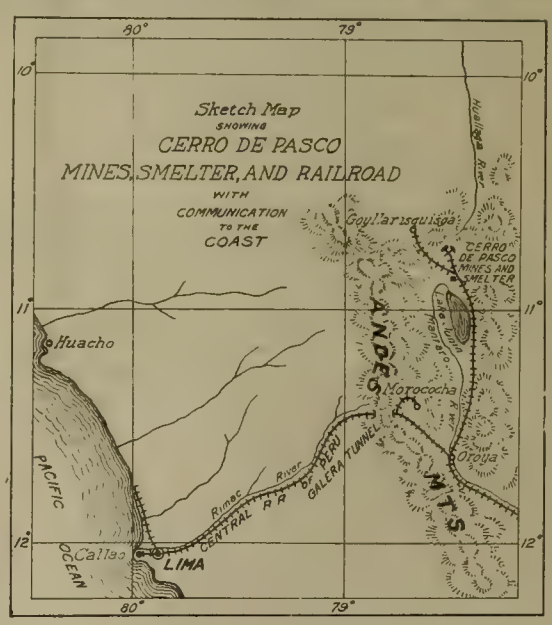
ZINC SMELTER FOR FOREIGN ORE AND CONCENTRATE—GERMANY AND AUSTRALIAN ZINC ORES—ANACONDA AFFAIRS—COPPER MINING NOTES—CERRO DE PASCO PUBLISHES YIELDS—BURMA CORPORATION

The report which was circulated around New York a while ago that the American Smelting & Refining Co would build a zinc-smelting plant on the Atlantic seaboard to handle the ore and concentrate shipped from Australia, has reached England and does not seem to be greeted with any enthusiasm there. There is no doubt that the Company was considering the matter of building a plant, but the question was put on the scheme by the decision in the friendly suit by the Zinc Corporation against Skipworth and others. The first decision was appealed to the Court of Appeal in London and was sustained, the court holding that the contract of the Zinc Corporation with Aron Hirsch & Sohn, by which the latter is to take the whole of the concentrate output of the Zinc Corporation up to 1919, was not abrogated by the war. The directors of the Zinc Corporation had proposed to abrogate the contract and to enter a new contract with the A. S. & R. Co., or else to erect a plant in England and treat the concentrate there itself. In the face of this decision, no American company would be willing to go ahead and spend the large sum required to construct a modern zinc smelter, with the prospect of having the concentrate supply cut off at the end of the war in Europe. This matter is also discussed in the London letter of this issue.

It is interesting now to note that the companies in Australia have been under suspicion because of their German affiliations, and offices of some of them have been raided. The attorney-general of the Commonwealth recently made the public statement that the investigation regarding the Broken Hill Proprietary and other metal companies had not disclosed any offense against the law, but the facts showed beyond all question that German capital and German influences exercised a monopoly over the civilized world's base-metal industry. The monopoly is so complete that it excludes effective competition. Peace holds out no prospects satisfactory or even tolerable to the British and Australian interests, since it will surely involve resumption of complete German domination of the industry. There seem to be grounds for the attorney-general's forebodings, for it seems scarcely probable that even if the Zinc Corporation attempts to proceed with its effort to abrogate the contract with the German smelters, that a zinc smelter in England would be a profitable venture. One of the critical factors in establishing such a plant is the labor supply, and the labor situation in England is not such as to cause an experienced zinc smelter to think that a smelting plant built there would be a financial success. The same is true, only more so, as regards the labor situation in Australia, and it indeed would appear as though the Australian zinc producers will have no option but to resume their German affiliations at the close of the war.

The Anaconda Copper Co. is making plans for changes in its practice after normal conditions are restored. It was some time ago decided to give up the hauling of ore from Butte to the Great Falls plant for concentration, as the extra freight cost as compared with concentration at Anaconda made this disadvantageous. Doing away with the concentrating renders available the hydroelectric power formerly used in the ore concentrating plant, and as he terms on which the Company leases the water power of Black Eagle falls gives it very cheap power, it was good economy to find some possible way of utilizing this. It is now announced that this will be done by constructing a new electrolytic refinery to have a capacity equal to the present one at Great Falls. This will raise the capacity of the Great Falls refinery to 240,000,000 lb. of copper per year. Most of this refined copper will, of course, have to go East, as the market for refined copper in the western states, and in the countries bordering on the Pacific, is rather limited, but as the new plant will have the advantage of cheap electric power and will furnish work for the old staff at Great Falls, it has obvious economic advantages. The smelting plant at Great Falls will be kept in operation, and the reconstruction which has been in progress for some time will be carried on to completion. The improvements in processes which have been devised by Anaconda officials in the last year or two will give a considerably greater copper output; and it is officially stated that when all these plants are in regular operation the Company will produce 50,000,000 lb. more copper per year than formerly from the same tonnage of ore. The Anaconda has declared a dividend of 25c. per share, payable on January 20.

The report that the North Butte and East Butte mining companies would be consolidated is officially denied.——The United States Smelting, Refining & Mining Co. has declared a quarterly dividend of 87½c. on the preferred stock, payable January 15, but no action was taken on the common



shares. The Mohawk Mining Co. is 'making hay while the sun is under a cloud.' Its recovery of copper from the ore milled reached 20½ lb. per ton, or over 2 lb. better than its best previous record. If it maintains its present rate of operation the output of copper this year will be almost equal to the best previous year.——The Wolverine made a recovery

of 19½ lb. of copper per ton of ore, but this is likely to steadily decrease, as it is estimated that the Wolverine has only about seven more years of life.

The Cerro de Pasco Mining Co., which has for years maintained a profound secrecy in regard to its operations in Peru, has recently made a statement to the *Boston News Bureau* of the amount of copper produced during the past three years. This is as follows: during 1912, 45,272,000 lb. refined copper; 1913, 43,865,000 lb.; and for 1914, 42,000,000 lb. is estimated. At present the smelter is operated at 40% capacity. No obvious purpose was served by the former policy of secrecy, since anyone who could materially profit by knowing what the production was could obtain the official records of imports, and it is not improbable that from henceforth the Cerro de Pasco will fall in line with the other copper companies and give out the figures as to its production and operations. It is reported here that the Copper Producers' Association will never resume the publication of its statistics, which were stopped at the outbreak of the war. The persistent reiteration of this probably indicates that some one would prefer not to have the figures continue to be given out.

The mines of the Burma Corporation at Bawdwin, on the border line between Burma and China, are of much importance and interest to producers of lead and zinc because of the unusual character of the ore. A recent report given out by the Company says that development work has proved the existence of about 500,000 tons of ore, and indicates 1,000,000 tons more of reasonably assured ore, the latter being of higher grade than the former. A recent cablegram says that at a depth of 168 ft., in a winze sunk from the 170-ft. level, the orebody averages 35 oz. silver, 36% lead, and 20% zinc. Diamond-drilling has, however, indicated that the orebody extends to at least 300 ft. below the 170-ft. level, and is even higher grade than the ore below. Present smelting operations are confined to the old slags left by the Chinese workers years ago. The problem how to smelt these ores at a profit is an interesting one, and while contracts have been made with Belgian firms to treat the material, it is hoped that some method can be devised which will permit smelting the ores at a larger profit.

WASHINGTON, D. C.

Leasing Oil, Gas, and Coal Lands.—Water-Power Bill.—Revision of Mining Laws Still Delayed.

The Senate Committee on Public Lands is giving hearings on the Administration's conservation measures which have already passed the House, and there is to be a thorough hearing on the so-called leaseholding bill, to which there is greater opposition than to any other measure of its kind in Congress. This provides for the exploration of oil, gas, and coal lands, but its essential principle is leaseholding, and the introduction of it is feared by many in the mining world. It is the plan of the committee to hold protracted hearings on this measure with the beginning of the new year, and western mining men should be represented if they wish to make a considerable showing against the proposal. It is, however, forecasted by western senators that Congress will take no action on the bill at this session, which has only two months more to sit. They plan to obstruct the progress of the measure so that it will fail, but nothing can be taken for granted. Those who are behind the measure, in the main the administration, through the able activity of Franklin K. Lane of the Department of the Interior, will try with great patience again in the next Congress. The representations before the Senate in this session will have no mean effect *pro* or *con* in the work on the legislation in the next session, should it remain unfinished business.

Western senators have been busy in hearings over the so-called water-power bill, which, while it does not affect mining directly, does so in an indirect manner. The mining and the water-power interests, through the state issues involved, are sailing in the same boat. A safe journey is likely to mean finished legislation provocative of more. In the matter of water-power, those who are opposing the federal legislation now before Congress are saying that nowhere is water-power now needed in the West, all states having a surplus of it. The legislation is therefore unnecessary, and will serve no other purpose than to project a principle of uneasy dimensions. In the public hearings, John Ryan, president of the Montana Power Co., declared it was folly to talk of the possibility of acquiring water-power sites for speculative purposes, holding them undeveloped. G. M. Dahl, director in the General Electric group, said that any monopoly in water-power, developed or undeveloped, was impossible. General Electric interests, he said, controlled 28,000 hp., and had less than 30% stock interest in the other companies named in the General Electric group; there is no concentration in the hands of a few interests as has been claimed.

Governor Ammons and Governor-elect Carlson of Colorado appeared before the committee. The former attacked the principle of leaseholding, on waterways as well as on coal, oil, gas, and precious metal lands. He declared that such a policy would deprive the public land states of the West of the taxes with which to build themselves up. Large areas of those states were held by the government, and, under a leasing system, only the federal government would profit by their development. Mr. Carlson said that experience has shown that private ownership was the only system under which the resources of the West could be developed.

The legislation in the House to create a commission to codify the mining laws of the land lies as dormant as ever. There is a mysterious influence at work to kill the proposal. Many promises are made only to be broken. Presently an effort will be made to smoke out the opposing forces.

HOUGHTON, MICHIGAN

Fires and Explosion at Copper Mines.—Mohawk Output.

The third recent disaster in the Michigan copper district occurred early Christmas morning when the stamp-mill of the Isle Royale Mining Co. on Portage lake, one mile east of Houghton, was completely destroyed by fire. It is believed that the fire started in the office on the floor of the mill, and in spite of the efforts of the mill hands and the Houghton fire department, the whole plant, with the exception of the carpenter shop, boiler house, and office, was burned to the ground. The loss is estimated at $250,000. The mill contained three Nordberg steam stamps, 72 roughing jigs, 30 finishing jigs, circular slime tables, and Bartlett and Wilfley tables. The mill is now a skeleton mass of twisted pipe and machinery. Men are now engaged in taking down dangerous pieces of framework, and saving as much as possible from the ruins. The 'rock' from the Isle Royale mine will probably be sent to the Centennial-Allouez stamp-mill at Point Mills.

On December 18 one of the boilers at the No. 3 shaft of the North Kearsarge mine of the Osceola Consolidated Mining Co. exploded. The boiler house was almost completely wrecked and the firemen killed. No. 3 shaft was put out of commission temporarily, and in the meantime the men employed at this shaft are getting No. 1 shaft into shape for operation.

Several weeks ago the boiler house and compressor plant at the Superior mine were destroyed by fire. This mine, however, is now back to normal production with a daily tonnage of 600 tons.

A new record was made during the month of November by the Mohawk Mining Co. The production of 1,262,864 lb. was lower than the production for October, but the yield of 20.45 lb. of refined copper per ton of rock exceeded the October record by more than two pounds.

LONDON

DEVELOPMENT RESULTS AND ORE TREATMENT PROPOSALS OF THE RUSSO-ASIATIC CORPORATION — SMELTING AUSTRALIAN ZINC ORES IN AUSTRALIA

In January last, discussion of the Russo-Asiatic Corporation and of the zinc-lead-silver-gold properties acquired by it in Siberia was published in the *Press*. The deposit receiving first attention was the Ridder, which is situated in the Altai territory not far from the Irtish river. The Company belongs to the group identified with the Kyshtim Corporation. Leslie Urquhart, the managing director, is an engineer of long residence in the Russian empire, while Herbert G. Hoover has lent his technological skill and financial resources. The

MAP SHOWING RUSSO-ASIATIC PROPERTIES.

to water concentration, flotation, and smelting. In the first place, ordinary flotation is not necessary, as the mineral does not slime badly and no heavy gangue is present. It was found that, though fine-grained, the constituent sulphides can be fairly well segregated on tables and differential flotation for the treatment of slime need not be considered at present. The plan therefore is to remove as much zinc as possible by water concentration, this concentrate to be roasted and smelted in retorts, while the lead-copper concentrate will be smelted for metallic lead and copper matte. The development of the orebody is in the hands of R. Gilman Brown, and an independent geological report has been made by H. H. Knox. The orebody has been traced along the strike for 750 ft. It is nearly vertical at the outcrop, and the dip soon flattens with depth. In order to test the ore at a lower point, two rows of five boreholes 125 ft. apart have been sunk, one row 400 ft. from the outcrop and the other 170 ft. farther away, both at an inclination of 63°. All these holes have passed through ore, and the assays of the cores are fairly uniform. The width of the solid sulphide portion varies from 20 to 90 ft., and that of the disseminated up to 200 ft. The results of the borings are such as to warrant an estimation of available ore. Down to 700 ft. on the dip it is calculated that there is 883,000 long tons of sulphide averaging 30.9% lead, 14.9% zinc, 1.37% copper, $8.60 gold, and 10 oz. silver, and 1,565,000 tons of disseminated, averaging 2.89% lead, 5.6% zinc, 0.3% copper, $12 gold, and 1.29 oz. silver. It will be seen that the gold content is high, and judging by the relative figures in the rich and disseminated ores, it would appear that gold is in the gangue as well as in the sulphide, though I am told that this is not the case, and that the gold is in the sulphides. It is intended to erect a concentrator of 200-ton daily capacity, to treat rich sulphide, and subsequently another plant of 400-ton capacity

Ridder property has been a hard nut to crack for years, and many have been the English, French, and American engineers who have had a look at it, and held up their hands in despair. The lode is wide, being as wide as 250 ft. in places, and containing zones of varying richness between the foot and hanging walls. The minerals are galena, blende, and chalcopyrite, with gold and silver. In the richer parts the gangue is quartz and calcite, the proportion of gangue being so low as to justify the use of the term of 'solid sulphides' by the directors. Beneath this zone is another containing sulphide in patches, and called 'disseminated ore,' the gangue being hornstone, which was probably originally a shale, but much silicified and brecciated. The oxidized zone extends to a depth of 140 ft. or so, and has been worked for the gold and silver by previous owners. To Mr. Hoover and his associated engineers, W. T. Madge and Deane P. Mitchell, the sulphides presented no terrors, for they have been highly successful in the treatment of Broken Hill ores. The study to ascertain the best way of dealing with the Ridder ore required the consideration of questions relating

to treat disseminated ore. It is estimated that a profit of $35,000,000 will be made from the treatment of the ore mentioned above. Of course, the whole of the output is readily marketable within the Russian empire. The development of this mine has been handed over this week to a subsidiary called the Irtysh Corporation. The Russo-Asiatic takes £1,100,000 in ordinary shares as purchase price. The capital required for development is being raised by the issue of £500,000 debentures carrying 6% interest, and subsequently exchangeable into shares. The Ridder is not the only property acquired by the Company, as the Ekibastus coalfield is included in the transfer. One of the seams is of excellent quality and will make suitable coke for smelting purposes. The smelter will be erected on the spot, and the concentrate shipped from the Ridder. Readers of the *Press* will be interested to observe that all the engineers whose names have been mentioned are, with the exception of Mr. Urquhart, Americans.

On several occasions I have referred to plans for erecting lead and zinc smelters in England, to treat the Broken Hill concentrate hitherto shipped to Germany. A serious snag in the path of the companies desiring to rearrange their policy in this connection promises to be the interpretation by the English courts of justice of the contracts under which the concentrate is sold. A case before the courts at present is that of the Zinc Corporation, in which judgment is desired as to the construction of the contract made in 1908 with Aron Hirsch & Sohn. This contract contains a clause to the effect that, in the event of anything happening beyond the control of the vendors and buyers, preventing the sale and delivery, the contract should be suspended during the cause of the disability. The judge in the first court gave it as his opinion that the clause covered the present position created by the war; knowing that the government and the parties involved desired the opinion of the highest court, refrained from giving any elaborate judgment. With unprecedented rapidity, the case came before the appeal court during the week ended December 12, before six judges. This court held the opinion that the matter could not be discussed in the absence of some representative of Aron Hirsch & Sohn, and dismissed the case. At the time of writing, I am not informed of the future intentions of the directors of the Zinc Corporation. As things stand at present, the matter is in exactly the same position of doubt as it was before it went to the court. As readers will remember, the Zinc Corporation was one of the first in the field at Broken Hill with a project for the treatment of zinciferous tailing by means of the flotation process. The Company has not only beneficiated enormous heaps of zinc tailing, but three years ago acquired a mine for itself on the Barrier range, the South Blocks, and has under option the South Blocks Extended. Thus it is a producer of lead concentrate as well as zinc concentrate. Active steps have been taken during the past three months with a view to establishing metallurgical works, and thus freeing Australia and England from German domination.

BUTTE, MONTANA

ANACONDA COMPANY'S EXTENSIONS, AND SAFETY FIRST WORK.—ELM ORLU AND BLACK ROCK ZINC MINES.—NORTH BUTTE AND EAST BUTTE COMPANIES.

Despite the low price of copper and the gloomy outlook caused by England's placing copper on the contraband list, the mining situation in Montana is good. The president of the Anaconda Copper Mining Co., B. B. Thayer, together with the president of Amalgamated Copper Co., John D. Ryan, recently completed a tour of inspection of the various interests of the Anaconda company throughout Montana. These gentlemen spoke optimistically of the future and outlined improvements, extensions, and enlargements, which will involve the expenditure of large sums in Montana, forthwith. One of the most important of these undertakings is the enlargement of the electrolytic refinery at Great Falls. It would appear that the cheap electric power at Great Falls justifies the local refining of the copper, and it is the apparent intention of the Anaconda in the near future to do much of its refining at Great Falls instead of in the east, as at present. The New York correspondent also discusses this subject in this issue. At the Anaconda works the sulphuric acid plant is being pushed rapidly to completion, and the new leaching process will soon be in operation. Significant experimenting is under way along other lines also at this plant. At Butte, the Anaconda company has manifested faith in the future of the copper industry by taking an option on the property of the Butte-Duluth Mining Co. at a price given out as over $2,000,000. It may not be the intention of the Company to continue the leaching methods now practised at Butte-Duluth, but the disseminated orebodies which are claimed to be extensive will be proved by thorough drilling.

The Anaconda company is giving a lot of serious attention to the 'safety first' movement. C. W. Goodale, manager of the Boston and Montana department, has been made chairman of the general committee having the work in charge, and the results are beginning to show for his careful and systematic direction. 'Safety first' committees have been organized throughout the mining and metallurgical works, and they have regular meetings. The latest innovation is a monthly publication called *The Anode*, which is to be devoted entirely to matters pertaining to the prevention of accidents. It is to be made readable and entertaining so that the employees will read it and profit by it.

Butte's two zinc mines are now at work full blast, treating about 1500 tons of ore per day. The Elm Orlu mine, belonging to the W. A. Clark interests, is shipping about 500 tons per day to the new mill of the Timber Butte Milling Co., and the Black Rock mine of the Butte & Superior Copper Co. has started again with its normal production of about 1000 tons per day. The success of these zinc mines is very significant here. It is well known that some of the mines of the Anaconda company contain large quantities of zinc ores, mineralogically not unlike the Elm Orlu. It is not improbable that Anaconda will be taking its zinc resources seriously before long and endeavor to prepare a commercial zinc product.

Rumor is persistent that the North Butte Mining Co. has bought the property of the East Butte Copper Mining Co. This is important news if true (according to our New York correspondent it has been officially denied.—EDITOR), as it indicates a further pulling apart of the Cole-Ryan interests formerly so closely linked. The North Butte company would thus become the chief competitor of Anaconda in the Butte field. What with its former holdings, its recent acquisition east of the Pittsmont, and now the acquisition of the Pittsmont itself, North Butte will become an important factor in Butte's mineral production. Incidentally, Anaconda will lose some custom ore, as North Butte is shipping to the Anaconda works at present. East Butte has a mill and smelter which North Butte will surely make use of. North Butte will also make use of the Pittsmont workings of East Butte to explore some of its own ground to the east. This consolidation should be of benefit to Butte, as it makes two strong independent copper companies, with the resultant activity in the purchase and development of new ground. The North Butte has taken the lead in this prospecting by the organization of the Rainbow Lode Development Co. for prospecting for zinc east of the Black Rock. Likewise the Anaconda takes a hand by prospecting the Nettie mine west of Butte. If these two Companies get in the habit of watching what the other is doing the district as a whole should profit thereby.

Butte interests are drilling for oil near Ryegate, in Musselshell county. The rig has 4000-ft. capacity.

THE MINING SUMMARY

The news of the week as told by our special correspondents and collected by the local press

ALASKA

Mining began in Alaska in 1880, and since that time the territory has produced mineral products to the value of $268,000,000. Of this, $244,300,000 has been in gold, $19,800,000 in copper, $2,251,000 in silver, $170,000 in coal, and the rest in tin, lead, quicksilver, marble, gypsum, petroleum, etc. Copper mining began in Alaska in 1901, and the total production is about 133,000,000 lb., according to Alfred H. Brooks, of the U. S. Geological Survey.

The total production of Alaskan tin mines since the industry started in 1902 is about 550 tons of metallic tin, valued at $432,000. In 1914 one dredge was operated on the Buck Creek placer tin deposits throughout the open season. Two others were operated for a part of the season on Anikovik river, working on deposits containing both gold and tin. Operations were also continued and some tin was produced at the Lost River lode tin mine. All these localities are on Seward Peninsula. Tin was also produced from several deep placer mines in the Hot Springs district, operated chiefly for the recovery of gold. It is estimated that nearly 50 tons of stream tin was recovered from these placers in 1914. This output could be considerably increased, for only a few of the miners make a systematic attempt to recover the tin.

ARIZONA

A week's heavy rain has resulted in flooding the country between Phoenix and the Mexican border. Several lives were lost, stock drowned, railways washed out, and an immense amount of damage has been done. Thirty miles south of Tucson the Santa Cruz valley suffered greatly. The Tucson Farms Co. lost 19 centrifugal pumps and other machinery worth $500,000. At Bisbee, floods flowed through the cañons between the hills and business area. The San Pedro river west of Bisbee was a mile wide. At Douglas the railroads were badly damaged. Nogales was surrounded by water.

Gila County

Minority shareholders in the Keystone property, which has been acquired by the Inspiration Consolidated, are to protest against its transfer, on the ground that enough is not being paid for it.

Greenlee County

The Arizona Copper Co.'s output in November was 2,670,240 lb. of copper.

Mohave County

Engineers representing San Diego people have sampled the Enterprise mine, 18 miles east of Kingman. The ores contain lead, gold, and silver.

Pima County

The Gold Nugget Placer Mining Co., holding dry placer deposits 47 miles from Tucson, has been absorbed by the Greaterville Dredge Gold Mining Co., which owns adjoining property. J. West, president of the latter Company, states that the purchase price was $75,000 and that 960 acres of ground was included in the transfer, this making the total holdings of his Company 1980 acres, which is being developed as rapidly as possible. A well, which is to furnish water sufficient for the dredge, has been practically completed and actual gold recovery is expected to start within the next six months.

Yavapai County

(Special Correspondence.)—An option has been given on the Gladstone McCabe claims at McCabe to J. C. Rankin, acting for an English company that is at present operating the Henrietta mine, according to John L. Davis, the manager. These three mines are practically together, and the intention of the Company is to connect them underground and hoist the ore through one well equipped working shaft. It is reported that a new modern reduction plant will be constructed if the option is taken up, as is expected. These are among the best known of the old producers of this district, as they have been worked continuously for a number of years and contain ore reserves for many more years of profitable extraction.

Prescott, December 28.

CALIFORNIA

Oil production of the state in November was 259,771 bbl. per day, shipments from the fields being 6,746,952 bbl. Stocks amount to 57,071,088 bbl. There were 6123 producing wells.

Fresno County

The geology and oil prospects in Waltham, Priest, Bitterwater, and Peachtree valleys are discussed by Robert W. Pack and Walter A. English in *Bulletin* 581-D of the U. S. Geological Survey. This area is part of the Coalinga field, but situated in the hilly region to the west, and was examined in the summer and fall of 1913. The immediate reason for the investigation was the need of geologic data for the classification of the public land in the area that had been withdrawn from all forms of entry, because of its possible value as oil land. As a result of the examination, large areas of unappropriated public land have been restored to entry. The chief conclusion reached regarding the occurrence of oil is that most of the region does not offer reasonable promise of yielding petroleum, and that much of it is certainly barren of oil. Coal occurs in the Tertiary beds in the Priest valley syncline and at several places in the hills on the south side of Waltham valley. Coal has been extracted from the Stone Canyon mine for many years.

Kern County

(Special Correspondence.)—At Randsburg the Consolidated Mines Co. is reported to have cut 4 ft. of $25 ore. For over a year the Company's mill has been crushing ore averaging $7 per ton.——Rumors connected with the Yellow Aster speak of a sale and a large stamp-mill to be built.——A flow of water from 10,000 to 15,000 gal. per day has been cut in an old shaft of the Good Hope and Wedge mines, right in town, and supplies the Consolidated mill.——Lessees are busy at several claims

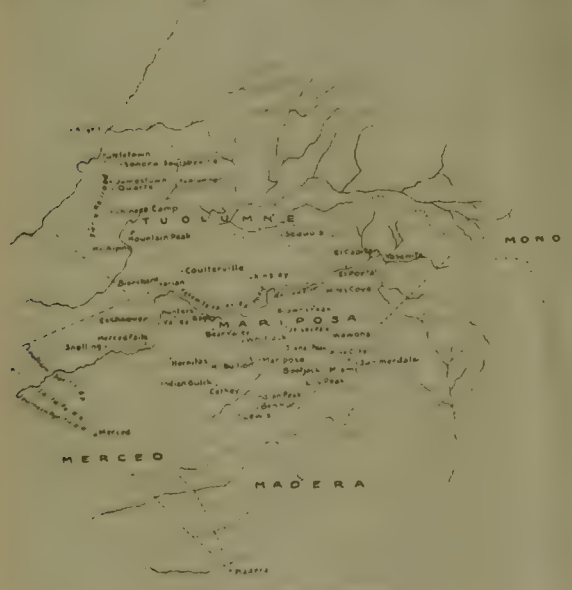
At Jawbone the wolfram claims of T. Whalley and F. Fellman are being leased, and work is to start soon. Low-grade tungsten veins have been found on these properties.

Randsburg, December 27.

Mariposa County

(Special Correspondence.)—The following notes cover this county's latest developments. A. G. Huberty, of Jackson, Amador county, has been in Mariposa for several days examining the Herman, Barbara, and Charles H mines, located 1½ miles west of Bear valley, owned by C. A. Schlagerter of Mariposa. The bond on this group is to be $12,500, due in 6, 12, and 18 months. There is a 210-ft. shaft on the property, about 100

ft. of adits, a lot of open-cut work, and 300 tons of ore on the dump which it is said will assay $12 per ton.——A bond has been taken by Frank X. Egenhof on the Little Wonder, owned by Mr. Keilburg and others, but Mr. Egenhof's sudden death last week will delay the development of this property.——A contract for driving on the 100-ft. level of the Sunshine mine has been let by Mrs. J. E. Divens to F. T. Schlagerter and partner. The second round of holes broke into high-grade ore which it is estimated will plate $100 per ton. The property is equipped with gasoline hoists and other good machinery. This mine produced 200 tons of ore last summer, averaging $12.50 per ton.——James C. Yancey, of Portland, Oregon, who recently bonded the Sweetwater and Revel mines and mills, has men under C. H. Wedekind building a dam to supply water for the Sweetwater mill and other improvements for economical work so much needed in Mari-



MAP OF MARIPOSA COUNTY.

posa mine development.——Schroeder brothers and Judkins, of Colorado, Mariposa county, will start a 5-ft. Huntington mill on the old Schroeder mine above Merced river, south of Saxon creek. The surface of this mine was rich, and as the ore is a soft decomposed material, this machine is adapted to the ore.——The Colorado Quartz mine, owned by Judkins, Weston, and Dearborn, has a new hoisting plant, and sinking on the vein is under way. It is predicted that this mine will become one of the steady producers of Mariposa county. ——The Mountain King Mining Co., on the Merced river, east of Bagby, has opened high-grade ore and is actively developing its property. The Company is installing some new machinery, and a mile of iron pipe for a new water-power plant. ——The Clearing House Mining Co. has started its mill, which has been closed down on account of low water. George W. Egenhof, manager, will install a power drill-sharpener in the near future.——The Malone mine, now owned by the Golden Reath Mining Co., will be sold under judgment of $1900 at Mariposa on December 21. Thomas Gordon is the principal creditor.——The Monte Cristo claims of Robert Weilman and associates, situated in Devil's gulch, are being developed and an engineer has been sent to New York expecting to place this property with New York and Canadian people.——The Comet mine is closed down, and probably will not resume operations before next spring on account of the snow.——The Silver-Lead mine is being developed by the new owners, who have erected a 10-stamp mill.——No. 5 mine is having a reduction plant installed by Mr. Parker of Chicago. This is a new style of ball-mill, first of the kind that has ever been used in California, and its operation will be watched with considerable interest.——The Mariposa Commercial Mining Co. has been repairing its power dam at Bagby, and has been making plans and surveying for a large dam between Mt. Bullion and Mariposa. This dam will be used for irrigation and power purposes.——There is little question but that Mariposa mines will be developed more in 1915 than they have been in the past five years. What is needed is to have intelligent and economical management, and with that the properties will soon resume their former production.—— The county commissioners are planning on installing a specimen case in each of the hotels of the Yosemite valley to show the minerals produced by the county.

Mariposa, December 20.

Nevada County

The regular quarterly dividend of the North Star company, of $50,000, has been paid, making $200,000 for 1914, and $4,186,989 to date. The dispute between the You Bet Mining Co. and the Goodwin estate has been settled, the former being in possession again. The Jerry Goodwin property is to be reworked at once.

Plumas County

Work has been stopped for the winter at the Haskell Peak mine near Clio. There is 54 in. of snow on the ground there. Good progress was made in the lower workings, which will open the gravel channel. J. J. Snyder is superintendent.—— The same channel is to be prospected by G. W. Wilson and others some distance away.

San Bernardino County

(Special Correspondence.)—All leases on the tungsten deposits at Atolia terminate on January 1. Only a few miners made any profit during the season, and not many, it is reported, are anxious to renew leases under present conditions, which are really only working contracts.

Atolia, December 27.

Shasta County

This county's mineral exhibit for the Exposition at San Francisco weighs over 50 tons, and is ready to be shipped from Redding. Large blocks of ores have been given by various mining companies.——The smelter fume case will be continued on February 23.

The Mammoth Copper Co. has bought the Friday-Lowdon 13 copper claims, near Kennett, for $5000. About 1000 ft. of development and considerable diamond-drilling, costing $50,000, has been done. Owing to the zinc in the Company's ore, a sorting plant is being built. The product containing an excess percentage of zinc will be sent to Oklahoma smelters.

Sierra County

At the Kate Hardy, at Forest, the mill is working 24 hours daily. According to the superintendent, A. D. Grant, the lower adit is in 600 ft., and six veins have been cut.——The vein has been found again in the North Fork at Forest. It consists of quartz and talc, the former containing considerable pyrite.——A fire at the Plumbago destroyed the 'dry' house and stable.——A fire at Pike City destroyed several buildings last week, including the Alaska Mining Co.'s hotel of 100 rooms, occupied by its miners.——Gravel has been opened by a rise in the Cold Spring claim near Mt. Vernon. Los Angeles people are interested.

Tuolumne County

It is reported that work is to be resumed at the old Soulsby mine, which has been a large gold producer from down to 800 ft. depth. Pumps are to be installed to cope with the water.

Lessees in the New Albany mine in the east belt of this county have opened rich ore at 700 ft. During 10 months they have not extracted much ore, but now they expect to keep the 20-stamp mill going.

Tulare County

The Woody, Eclipse, Ball Mountain, Josephine, and other claims of the Adams Corporation, in the White Pine district near Porterville, have been acquired by W. T. Young of Mississippi. The Ball Mountain was then leased to other people. A hoist and 15-ton mill on the Eclipse are to be moved to the Ball Mountain. There is said to be a good tonnage of ore in the claims.

COLORADO

Production figures for 1914, December being estimated, from the U. S. Geological Survey, are quoted under various counties.

Boulder County

This county's production in 1914 was $97,000 gold, 207,000 oz. silver, 450,000 lb. of lead, and 48,000 lb. of copper, an increase of $28,000 gold, 45,000 oz. silver, 40,000 lb. lead, and 22,000 lb. copper.

The new cyanide plant, situated at Caribou, 35 miles west of Boulder, built by H. P. Lowe and others at a cost of $60,000, to treat ore from the Caribou, Poorman, and No Name silver mines, is in operation. The mill is producing three carloads of concentrate per week. These mines have yielded a large quantity of silver, but have been idle for over 20 years. About $50,000 has been spent in unwatering them to 1000 ft., retimbering, and equipment. Over 50 men are employed at 800, 900, and 1000 ft. stoping ore. Dumps contain good ore also. An adit is in 1500 ft. in the Caribou, and is to be driven about 4500 ft. in all, to work the properties, which cannot be done profitably by the shafts.

Chaffee County

This county produced $480,000 gold, 260,000 oz. silver, 3,600,000 lb. lead, 300,000 lb. copper, and 2,000,000 lb. zinc in 1914, a considerable increase for all the metals except zinc, which equaled the 1913 yield.

Clear Creek County

The output of this county in 1914 was $540,000 gold, 432,964 oz. silver, 2,700,000 lb. lead, 450,000 lb. copper, and 1,000,000 lb. zinc, an increase of $70,000 gold, and small increases for silver and copper, but a considerable decrease for lead and an appreciable decrease for zinc.

Eagle County

Eagle county's output in 1914 came chiefly from Red Cliff, but included a small quantity of silver ore from the Lady Belle and North Dakota mines, in the Brush Creek district. The total yield was $45,000 gold, 116,000 oz. silver, 1,100,000 lb. lead, 30,000 lb. copper, and 7,664,000 lb. zinc, a small increase for gold, decreases for silver, lead, and copper, and 1,000,000 lb. increase for zinc.

Gilpin County

Last year's output was $500,000 gold, 150,000 oz. silver, 500,000 lb. lead, and 600,000 lb. copper, including ore mined through the Newhouse tunnel.

Gunnison County

Owing to increased shipments of lead ore from Italian Mountain, and of lead-zinc from Whitepine, there was an increase for lead and zinc in this county in 1914.

Lake County (Leadville)

Lake county, chiefly from Leadville, but also from the Lackawanna gulch and St. Kevin districts, produced $1,554,000 gold, 3,860,000 oz. silver, 27,000,000 lb. lead, 2,470,000 lb. copper, and 79,000,000 lb. zinc, with a total value of $9,000,000, against $1,023,631 gold, 3,400,318 oz. silver, 29,286,183 lb. lead, 1,923,987 lb. copper, and 93,842,857 lb. zinc, with a total value of $7,219,443. In 1913 the output of zinc carbonate was 111,000 tons of 24% zinc against 135,760 tons of 27.4% in 1913. The zinc sulphide smelting ore and concentrating ore combined increased from 97,704 tons of 23% zinc in 1913 to 114,000 tons of 22% zinc in 1914.

Leadville men are organizing a syndicate to tunnel and prove the area under Canterbury and Prospect mountain. The ore-shoots from Fryer and Breece hills dip north toward this ground. Cold weather has interfered with work on Breece hill and other parts of the Big Evans district. Lessees at the Jonny and the Ibex are steadily producing a heavy tonnage of gold, silver, copper, and zinc ores. At the Lapplander in Lake Park, W. H. Upton and others have opened 6 to 7 ft. of $18 to $24 ore in an adit 740 ft. long. Gold predominates in the ore. According to G. W. Buehler of the Miller mine in Lackawanna gulch, the property is looking better than at any previous time. Bad roads work against development in this area.

Mineral County

Creede produced $18,500 gold, 643,000 oz. silver, 1,450,000 lb. lead, and 36,000 lb. copper, but no zinc last year, an appreciable decrease for gold, silver, lead, and zinc.

Pitkin County

The Pitkin County (Aspen) yield last year was 354,000 oz. silver and 22,200,000 lb. lead, a decrease of 200,000 oz. silver, but an increase of 5,000,000 lb. lead. But for the fire in the Smuggler workings the output would have been even larger.

Summit County

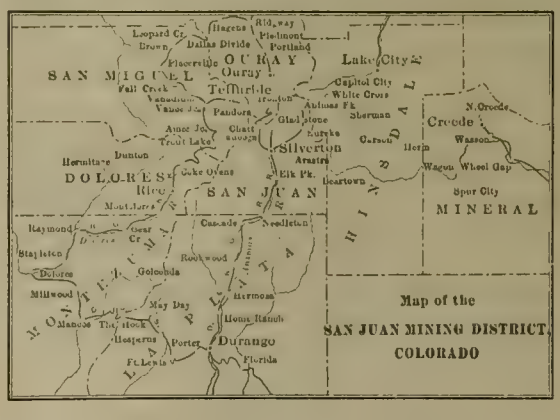
The output of gold from dredges and pocket mines at Breckenridge was $665,000 in 1914, an increase of $230,000. The total output of the county was $700,000 gold, 63,000 oz. silver, 1,300,000 lb. lead, and 5,000,000 lb. zinc.

(Teller County) Cripple Creek

According to the U. S. Geological Survey, the gold output of Cripple Creek was $12,048,000, an increase of $1,143,000. This is the largest production for any one year since 1908. Cripple Creek to the end of 1914 has produced $259,000,000 in gold.

The San Juan

The San Juan region of Dolores, La Plata, Ouray, San Juan, and San Miguel counties produced $3,721,000 gold, 2,470,000 oz. silver, 12,820,000 lb. lead, 2,490,000 lb. copper, and approximately 1,400,000 lb. zinc, compared with $4,071,683 gold, 2,769,077 oz. silver, 21,740,502 lb. lead, 3,373,935 lb. copper, and



6,867,410 lb. zinc in 1913. There were increases for gold of $30,000 in Ouray county and of $10,000 in Dolores, but decreases of $159,000 in San Juan, $42,000 in San Miguel, and of $192,000 in La Plata. There were increases for silver of 137,000 oz. in San Miguel and 90,000 in Ouray, but decreases

of 386,000 oz. in San Juan, 60,000 oz. in La Plata, and 80,000 in Dolores. Dolores county (Rico), San Juan county, and San Miguel county all showed heavy decreases in lead, copper, and zinc. The Tomboy company produced no zinc concentrate, as the Montana vein contains little or no zinc. Ouray county, because of increased production at the Camp Bird, the steady production of the Wanakah mill and copper matting plant, and the successful application of flotation to the Atlas ores, showed appreciable increases for gold, silver, and copper output, and a small increase for lead.——The boarding and bunk house of the Gold Lion mine, 10 miles south of Ouray, has been burned. The loss is about $15,000. It was one of the best in Colorado. John Davey is manager for the Company.

IDAHO

Blaine County

Ore averaging 10 oz. silver and 55% lead is being mined from the 500-ft. level of the Wilbert, 25 miles east of Arco. The mill, which is temporarily shut down, has had a Symons disc crusher added.——At 750 ft. in the Nau Aug. 12 miles from Hailey, two new ore-shoots are being opened. Ore being shipped assays 80 oz. silver and 62% lead. Concentrate is produced by the new mill. Dumps on the surface contain 12,000 tons of $14 ore. K. C. Wooley is in charge.

Shoshone County (Coeur d'Alene)

The Caledonia Mining Co. has distributed a dividend amounting to $36,079. Another of 2c. per share will be paid on January 5, making a total of $218,429 since October 5. A flotation process is now operating in the mill and adding considerably to the profits. Only 30 miners are employed extracting the rich ore.——The Hecla Mining Co. paid $220,000 in 1914, and $3,190,000 to date. A large tonnage of ore is available for the mill. ——According to the manager of the Laclede mine, F. Cushing Moore, in the Mullan district, development is promising for the 200-ft. level.——In the suit of the Marsh Mining Co. *v.* the Washington Water Power Co., the latter has compromised with the former over power rates.——In the suit of the Marsh Mining Co. *v.* the Inland Empire Mining & Milling Co., involving the right of the former to appropriate part of the surface ground of the Never Sweat claim, about 3.3 acres, to be used as a terminal for a tramway, ore-bins, etc., Judge John M. Flynn decided in favor of the plaintiff.——Developments in the Interstate-Callahan are most encouraging. On No. 4 level the ore-shoot is 1200 ft. long, and from 20 to 50 ft. wide, assaying up to 60% zinc. A shaft was sunk 450 ft. from this level and a cross-cut has opened 8 ft. of good grade ore.——The Pine Creek district is showing several interesting developments.

MONTANA

Silverbow County

The Anaconda Copper Mining Co. will pay a dividend of 25c. per share on January 20. At 1600 ft. in the Butte-Ballaklava, the Jessie vein shows 30 in. of glance. The 1600-ft. level is considerably better than at 1400 ft., the shoot being 200 ft. long on the former, and 140 ft. on the latter, copper content being about the same. Ore shipments of 50 tons per day are being made. Charles W. Newton was superintendent, but has gone to another property.——Directors of the North Butte company recently met at Duluth, Minnesota, and decided not to pay the quarterly dividend on account of large expenditure at the mine. Sinking the Granite Mountain shaft to 3100 ft., etc., cost $220,477 to December 1. The new hoist and other equipment will cost $246,956.

NEVADA

During 1914, 804 persons sent in 1631 samples from 248 localities, and the State Mining Laboratory made 6533 determinations on these samples. This is an increase of almost 50% over the number of persons and samples for 1913. Those sending samples would derive much greater benefit from its work, if they all took large samples and crushed them down and quartered them and finally sent a considerable quantity to the laboratory, than if, as is commonly the case, they sent only a few fragments.

Elko County

The Dexter mill and cyanide plant at Tuscarora has been destroyed by fire, the loss being estimated at $150,000. It has not been operated for several months, and arson is suspected.

The *Nevada Mining Journal*, devoted exclusively to mining in Nevada, is being published weekly at Elko. A preliminary issue has been made.

Esmeralda County

Drifts from the station at the top of rise 503-C, above the 1017-ft level of the Velvet claim of the Jumbo Extension are out 50 and 60 ft. respectively, showing 5 ft. of $50 and $60 ore. Daily shipments are 100 tons assaying $55 to $60 per ton. A stope above 921 ft. is opening 4 ft. of $25 ore.——The Jumbo Junior Mining Co. has been organized to work the Spearhead Fraction claim. A shaft was sunk 300 ft. several years ago. Sinking will be resumed to the latite-shale contact. The property is well situated.——The Kenanas winze is 75 ft. below the 700-ft. level.——The Black Butte shaft is being unwatered.

Nye County

Six mines at Tonopah produced 10,565 tons valued at $216,130 during the week ended December 26.——The Belmont company paid each employee $5 as a Christmas present. Likewise the Jim Butler men, under the same management.—— Six feet of $15 ore, with a 2-ft. vein of rich ore on the hanging wall, has been opened at 500 ft. in the West End. This discovery is in a little prospected portion of the property.—— All testimony has been taken in the Jim Butler-West End suit. Argument will be started on January 25.——Water in the Cash Boy shaft is down to 65 ft. below the 1100-ft. level, and should soon be all out. Sinking is then to be resumed to 1400 ft.——The North Star sent 100 tons to the West End mill last week.

At the Round Mountain mine a station has been cut at 1000 ft. A drift on the foot-wall of the new shaft vein has opened $51 to $281 ore. At 950 ft. this shoot was 30 ft. wide, the foot-wall portion assaying $80 per ton. Good results are coming from the Sphinx claim, especially at 800 and 900 ft. The pipe from Jett cañon, 8½ miles long, should be delivering water in May. It will carry 400 in. for the gravel deposit.

White Pine County

The Ely-Gibraltar Mining Co., operating 2½ miles north of McGill, has shipped ore worth $5000 to Salt Lake City. The last carload averaged 79% lead, 3 oz. silver, and 40c. gold per ton. An adit is in 950 ft. in tough ground. A mill is proposed for second-grade ore. C. E. Street, of Salt Lake City, is manager.

NEW MEXICO

Socorro County

The Socorro Mining & Milling Co., on application to the state engineer's office, has obtained an extension of two years for the completion of its hydro-electric plant, work on which has been in progress about three years. The Company has already expended $90,000, and the total cost will be at least double that amount. The plant will have an initial capacity of 1000 hp., and is designed to furnish power for the operation of the Company's mine and mill, and other mines and mills in the Mogollon district of this county. Oil-engines now are being used in that district, but the operating cost is high, due to the necessity of transporting oil overland from Silver City, a distance of 90 miles.

The Mogollon district, which in 1913 yielded $619,886 gold and 1,306,766 oz. silver, showed a small increase for 1914.

UTAH

Juab County

The annual report of the Colorado Mining Co., for the year ended November 1, 1914, shows that under the leasing system 2947 tons of dry ore was shipped containing 0.116 oz. gold and 33.106 oz. silver per ton, also 17.93% lead and a little copper. The gross value was $28.56 and net return $21.09 per ton. Royalties payable are from 20 to 50%, according to the value of the ore, from $10 to $30 and over per ton. Lessees received $28,274. The Company's revenue from all sources was $153,619 and at the end of the year had $84,624 on hand. E. F. Birch is assistant general manager for the Company.

Lead-silver concentrate is being shipped by the Utah Minerals Concentrating Co., which has a new plant treating dump material at the Chief Consolidated mine at Eureka. A crusher, rolls, tube-mills, and tables have a capacity of 100 tons per day. George W. Parshall is mill superintendent. ——The zinc orebody at 1200 ft. and the lead-silver shoot on the same level are developing well in the Tintic Standard at Tintic. E. J. Raddatz is manager.——Four feet of 125-oz. silver ore has been opened in the May Day. J. C. Dick is manager.

Salt Lake County

The Columbus Extension company is now controlled by A. O. Jacobson and associates. Miners are driving an adit to cut the same contact rocks in which the Cardiff ore occurs, about 4000 ft. away. Machine-drills are used.——Smelter returns from ore sent by the Wasatch Mines Co.'s Columbus Consolidated, in the Alta district, yielded $75 per ton net.

Tooele County

At the Buffalo Consolidated, in the Ophir district, ore assaying 150 oz. silver, 0.21 oz. gold, and 10.8% lead is being blocked out. Two shipments sent out by a lessee contained 136.8 and 164.1 oz. silver, 0.21 and 0.20 oz. gold, and 10.4 and 11.5% lead respectively.

WASHINGTON

Okanogan County

A new furnace to treat antimony ore from the Lucky Knock mine, near Whitestone mountain, is to be installed, according to advice from Tonasket. The deposit is considerable, and near a railway.

CANADA

British Columbia

The steamer *Amur* recently arrived at Seattle from Granby bay with 550 tons (1,100,000 lb.) of copper from the Granby company's smelter at Anyox. This is the first shipment for some time.

Ontario

The Beaver Consolidated shaft is down 920 ft. The rich shoot cut at 530 ft. has been proved at 460 ft. also.——The Nipissing company will pay a 5% dividend on January 20, amounting to $300,000. On December 19 the financial position was as follows: cash in bank, $401,410; bullion in transit, $420,937; ore on hand and in process, and bullion ready for shipment, $467,206; total, $1,289,553. About 600,000 oz. silver has since been sent to England.——During the year ended October 31 the Coniagas mine produced 2,497,395 oz. silver, about 1,000,000 oz. less than the previous year. The output to date is 20,160,389 oz. Dividends amounted to $1,320,000, making $7,000,000 since November 1906. Ore reserves are estimated to contain 11,904,000 oz. Cost of mining and concentrating was 12.444c. per oz., including all general charges and royalty, but not shipping, smelting, refining, and marketing, which totaled 3.585c. per ounce.

The Dome Lake, at Porcupine, has shipped its first bars of gold.

PERSONAL

Noel Cunningham is in Arizona.

A. C. Lawson has returned from Tonopah.

E. H. Lysle was in Los Angeles this week.

William H. L. Benedict is in San Francisco this week.

S. J. Kinnon is manager for the Ernestine company at Mogollon, New Mexico.

C. W. Purington has returned from the Lenskoi mines and left London for Boston, December 15.

Howland Bancroft has gone to British Columbia, expecting to return to Denver about the middle of January.

Albert Burch has resigned as manager for the Goldfield Consolidated Mines Co., retaining his position as a director and consulting engineer. J. W. Hutchinson has been made general manager and K. M. Simpson assistant general manager.

Obituary

Hugo DuBois, secretary for the Roessler & Hasslacher Chemical Co., a member of the American Electrochemical Society since March 27, 1909, died August 13, 1914.

A. K. Beatson, who died December 16 at Los Angeles, was most generally known as the discoverer and long time manager of the Bonanza copper mine on La Touche island, near Valdez, Alaska. He was one of the older generation of Pacific coast mining men, and prior to going to Alaska had been actively connected with various mining enterprises in California. One of the tunnels now used by the Great Western Power Co. was driven by him originally in connection with mining. He was long superintendent for the Big Bend T. & M. Co. In 1901 he was one of the original locators of the claims on La Touche with which his name is especially connected, and he managed the property up to 1910, when control was purchased by the Guggenheims, Beatson remaining a director. Since 1910 he has lived in California. The La Touche, Bonanza, which is often confused with the other Bonanza mine owned by the Alaska syndicate at Kennicott, stands as a monument to his insight and persistence in the face of many difficulties and discouragements.

SCHOOLS AND SOCIETIES

The annual meeting of the American Institute of Mining Engineers will be held in New York February 15 to 18 inclusive.

The annual meeting of the Mining and Metallurgical Society of America will be held at the Engineers Club, New York, January 12.

The American Institute of Electrical Engineers held its 302nd meeting in New York on December 11. Two papers discussed the subject of insulators.

The Utah branch of the A. I. M. E. will hold an executive meeting at Salt Lake City on January 15. The necessary committees and program will be arranged for 1915.

The Geological Society of America will meet at San Francisco the first week in August in connection with the meeting of the American Association for the Advancement of Science. The Cordilleran section of the Society will act as host.

The Faraday Society held its annual meeting in London on November 23. Sir Robert Hadfield, of steel fame, was elected president for 1914-15. Several interesting papers were read.

THE MARKET PLACE

Weekly Summary of Prices of Shares and Metals

Metal Prices

San Francisco, December 31.

Antimony	15 —15¾
Electrolytic copper	13½—14
Pig lead	4.05—5.00
Quicksilver (flask)	$52.50
Spelter	7 — 7¼
Tin	34½—36
Zinc dust, 100-kg. zinc-lined cases	9

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, December 31.—Copper is quiet at 12.75c., lead dull at 3.80c., and spelter steady at 5.40c. per pound. November outputs of Chino, Nevada Consolidated, Ray, and Utah Copper were 3,047,694, 2,612,071, 3,196,457, and 6,668,040 lb. respectively. Inspiration balance sheet as at October 31 shows $2,195,231 cash.

COPPER

Prices of electrolytic in New York, in cents per pound.

June	14.71	13.60	Dec.	14.25	....

The copper market held steady last week, which was satisfactory, as present domestic consumption is not much over 50% of normal. There has been talk of the possibility of increasing the output if the price continues to rise, but this can hardly happen, as refineries undoubtedly have large stocks, with no immediate prospect of reducing them.

LEAD

Lead is quoted in cents per pound or dollars per hundred pounds, New York delivery.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Week ending			
Dec. 3	55.00	Dec. 17	52.50
" 10	52.50	" 24	53.00
		" 31	52 50

The market is somewhat weak and erratic. Cobalt mines are sending large quantities to England. In the week ended December 19, exports totaled 320,377 oz., and during half of the next week the total was 375,519 oz. The Beaver Consolidated has 200,000 oz. at the mine. The tone in England has been fairly good, according to Samuel Montagu & Co. Purchases on account of China have afforded some competition, and have put a little animation into the market. The demand for this quarter arises from the approach of the Chinese New Year, which commences on February 14, 1915.

The recurrence of this festival each year is accompanied with a settlement of outstanding accounts between the Chinese. They are keen speculators, and holders of cash naturally attempt to tighten rates at this period, and silver has to be bought in this market as a counter stroke. The silver may or may not be shipped actually to China. In any case, buying goes on more or less until the contending parties come to terms. For this reason any hardening effect upon prices from these purchases, made just before the Chinese New Year, may prove but temporary, for the silver thus acquired, or a portion of it, may be re-sold when the cash holder has lost his power to squeeze. The amount of supplies each day during the second week of December in London has been singularly unequal, and as demand also has been erratic, the result was curious. The price has risen when supplies have been large and fallen when they were exceptionally small.

Exports of silver from London to the Orient to December 10 totaled £5,099,500, or say 51,000,000 oz., less than in the same period of 1913.

Current Prices for Oils and Candles

(Corrected monthly by Standard Oil Co. California.)

All prices are f.o.b. San Francisco except where otherwise specified, and are subject to change without notice.

Granite Mining Candles	Per set, cents	Granite Mining Candles	Per set, cents
6s-12 oz.-10s	8¾	6s-14 oz.-20s	9½
6s-12 oz.-20s	9	6s-16 oz.-10s	10

Cyanide, sodium, 51% cyanogen, per lb.	0.25
Sodium, metallic, in 1-lb. tins, per lb.	0.40

Further progress has been made in re-establishing general normal prices.

New York Metal Review

The last month of 1914 was a quiet one in all the metals so far as domestic demand went, but the situation was helped out by sports of buying for export or for the manufacture of goods which are to be exported. This was notably so in copper, lead, and spelter. The tone of the market is more cheerful than it has been, and it is believed that domestic consumers of copper will enter the market strong in January. The decision of the Interstate Commerce Commission, granting to Eastern railroads an increase in freight rates, has had a good effect, although the companies have not yet released on board-cars requisitions. Their needs are known to be great, but while this is so, it is thought they will proceed conservatively, despite the favorable decision. But no one denies that they will be a more nearly normal factor in the market. In iron and steel lines there was better buying, especially for first-quarter delivery in December, but it was done at rock-bottom prices, which the market already is showing a tendency to leave. The heavy buying of various kinds of machinery for export has continued, and the total of sales runs into millions. The United States Steel Corporation announced that it would not cut wages, a proposition which had been discussed, and Mr. Gary, the chairman, made the statement that there are evidences of a change for the better. Wall Street houses are restoring their employees to three-quarters or full pay, money is easier, and the Christmas retail trade in New York city was better than merchants had expected it would be. Copper advanced, and lost but little after the rise. Exports of lead and spelter had been heavy, and the latter advanced in price. The tin market was quiet, and prices were fairly even, despite a scarcity of spot metal. Antimony declined in a dull market.

COPPER

December opened and finished quietly, though events of the month caused prices to rise, and the advance was held fairly well. In the first eight days, the quotation for electrolytic was 12.75c. cash, New York but on December 9 there was an advance to 12.87½c. Then came frequent advances until December 15, when the New York quotation was 13.37½c. cash, a level which was maintained until December 21, when there was a drop to 13.25c. Up to the time 12.75c. cash, or 12.87½c. 30 days, delivered, was reached, a large business was done, but consumers refused to follow the market up. In the first week of December the larger selling agencies made an effort to establish 13c., full terms, as the market, but the buyers would have none of it, and 12.75c. cash was adhered to for the time. It should be noted that at this time future deliveries were commanding an advance of about ½c. over prompt copper. The cause for the advances which started December 9 was heavy purchasing on the part of Europe. At no time was domestic demand for electrolytic anywhere near normal, and the trade does not expect much activity on the part of home consumers until about the middle of January. Lake copper, on the other hand, has sold well as a direct or indirect result of the war. Certain brands of some producers of Lake are understood to be practically exhausted. The quotation for prime Lake on December 1 was 13c. cash New York, but on December 11 it started upward, advancing ½c. per day, until 13.62½c. was reached December 15. The following day the price declined to 13.50c., where it was December 24. Good business was done at 13.50c., and still more could have been done had sellers been willing to grant concessions. Special brands of Lake commanded premiums. According to statistics prepared by the Department of Commerce at Washington, the copper exports to Europe in the first three weeks of December reached a total of 30,724,367 lb. Of this amount, nearly half, or 14,862,158 lb., was exported in the week ended December 19. France took 6,976,996 lb., Italy 3,457,042 lb., and England 3,209,461 lb. in that week. Henry R. Merton & Co., London, reported the stock of copper in Europe, November 30, to be about 31,749 tons, against 31,565 tons November 14, and 19,757 tons November 13, 1913. On December 1 the quotation for hot-rolled sheet copper was advanced ½c. to 18c., and again on December 15 to 18½ cents.

LEAD

The trade was greatly surprised when the largest producer announced a reduction of 10 points, November 28, making the New York price 3.80c. and that at St. Louis 3.67½c., quotations which held until late in December, although the St. Louis market showed weakness. Prior to the drop, the metal was regarded as strong. The most plausible reason for the cut was that outside sellers had been cutting 3.90c. While the domestic demand was poor, exports were good. The largest consignment of pig lead which ever left this country was aboard the steamer *Indrakuala*, which cleared for Vladivostok in November. On the steamer *Kursk*, which cleared for Archangel, November 20, was 1300 tons. In England metal for early delivery was reported as scarce on December 11.

SPELTER

Heavy buying of spelter for foreign consumption sent quotations up in December, after which came a decline, but not all of the advance was lost. The New York prices were as follows: December 1, 5.35c.; 8, 5.65c.; 15, 5.80c.; and 22, 5.65c. Russia has been a heavy buyer of spelter. In England the imports totaled 6432 tons in November, only half of what they were in the same month a year ago. A factor in sustaining the market is the fact that the supply of ore is not over plentiful.

TIN

Throughout December the spot supply of tin was short, and had there been any big demand prices would have soared. Up to December 24, only 650 tons had arrived, though on that day there was 2585 tons afloat. Nearly all of the latter, however, was due to arrive December 31 or early in January, and consequently could not be used to make December deliveries. The quotation December 1 was 33.15c. New York; 8th, 32.50c.; 15th, 34.75c.; and 22nd, 33.30c. Buying was spotty and mostly for future delivery. A curious circumstance was the buying of about 200 tons of tin in the New York market for export to Russia. This the trade could not understand, as London would seem to be the natural market for Russia. The announcement of the freight rate advance granted to Eastern railroads tended to stimulate the market, but the effect was not great. The stock of unsold Banca tin in Holland, November 30, was 3944 tons, against 160 tons on the same date in 1913. The deliveries in November totaled 2600 tons, of which 400 tons came from Pacific ports.

ANTIMONY

The market was dull and prices were weak throughout the month. The quotations December 1 were 17 to 18c. for Cookson's, 15 to 16c. for Hallett's, and 13.50 to 14.50c. for Chinese. December 24, prices quoted were 14.50 to 15c., 13.50 to 14c., and 12.50 to 13c., respectively.

ALUMINUM

Spot aluminum in ton lots was nominally quoted at 18 50 to 19.50c. at the end of December.

JOPLIN ore prices the last week of 1914 were the highest they attained in 1914, the basis range being from $50 to $52, basis of 60% metallic zinc. Few producers accepted as low as $50, base, while, on the other hand, not a great many carload lots brought as high as $52. An average settlement of $51.50 was made, with the buying extremely heavy, with the exception of one high-grade ore buyer.

COMPANY REPORTS

GREAT FOULDER PERSEVERANCE GOLD MINING CO. LIMITED

During the quarter ended September 30 1914, this Kalgoorlie company did 1,429 ft. of development. Work on the lode near the main shaft at 2200 ft. promises to yield profitable ore. The stock of broken ore in stopes is 233,440 ons, assaying $5.76 per ton. The mill treated 67,097 tons, yielding 16,258 oz. gold and 3155 oz. silver worth $326,000. Working costs totaled $4.25 per ton, and the profit above operation and capital expenditure was $44,000.

KALGURLI GOLD MINES, LTD.

The report of this Kalgoorlie company covers the year ended July 31 1914. Development footage totaled 2665 ft. also 427' ft. of diamond-drilling and 2638 ft. of sample holes. The drill was used extensively for testing the deeper ground, but nothing encouraging was discovered. On or below 1850 ft., 2778 ft. of drilling has been done in calc-schist, the ore-bodies on the east and west on reaching the contact between this rock and quartz-diabase split up and apparently gradually cut out. The opinion of J. Malcolm Maclaren, as published in the *Press* of November 8, 1913, has been confirmed in this work. Reserves, although difficult to estimate, are placed at 200,000 tons, according to the general manager, R. S. Black.

The mill treated 127,870 tons of ore with 92.43% extraction. The income was £256,185, of which the profit was £101,330. Adding £11,121 from the previous year, there was available £112,451, of which £96,000 was paid in dividends, leaving a balance of £16,451.

The output to date is as follows: 1,348,290 tons, £3,604,692 gold, and £1,444,500 in dividends.

STRATTON'S INDEPENDENCE, LTD.

The report of this well known Colorado company deals with the year ended June 30, 1914. The report of the consulting engineers and acting managers, Philip Argall & Sons; the mine superintendent, Erick Johnson; and mill superintendent, W. H. Harrison, contains the following notes:

Development totaled 2311 ft. on Company and lessee account. There were 66 men employed by the Company, of whom 33 were mining on the surface, and 44 lessees' men. Development was mainly directed to proving the mill veins at greater depth, and following them south into the granite area. This resulted in opening new ore, as over 93% of the shipping ore on Company account came from these veins. They are the sole source of shipping ore mined by the Company, and have yielded $237,992 to date. The estimated output for the current year is 60,000 tons. The grade is low, having averaged $2.84 per ton during the year under review. Work on the southern spurs of the Bobtail vein on No. 2 and 4 levels was not satisfactory. Lessees' operations in the Independence claim did not yield anything important. The Washington claim is still worked under lease. The vein at 1150 ft. is worthless. The claim produced $25,258 net, yielding a royalty of $7935. As the mill veins may pass into this area, the output may increase this year. The output of the Company and lessees in the whole property showed a decrease of $29,277 and $53,832 respectively, compared with last year. The dumps are now scattered and are costly to remove, but there should be enough for the mill for two years.

Lessees shipped 7783 tons of sorted ore valued at $158,173, against 10,314 tons and $229,528 in the previous year. Freight and treatment cost $48,744, while the royalty, etc., to the Company was $34,992, or 31.97%, leaving $74,437 net. The mill treated 369 tons of lessees' ore, giving $1068 net and $[illegible] to the Company. Sorted ore shipped amounted to [illegible] tons, worth $[illegible], against 420 tons and $[illegible] last year. After paying freight and treatment there was a net return of $[illegible]. Company ore to the mill was [illegible] tons, averaging $[illegible] per ton, yielding a profit of $[illegible], compared with [illegible] tons, $[illegible] and $[illegible] in the previous term.

The mill treated a total of 133,875 tons of mixed ores, and made a profit of $[illegible]. Details of costs, etc., will be given in another issue of this journal.

The revenue account of the Company shows a net total of $[illegible], of which $[illegible] was net profit. Adding the previous balance of $[illegible] there was $95,000 available. A dividend of [illegible] was paid on December 10, amounting to $29,800. Cash on hand and in banks in London and Cripple Creek totaled $98,000.

ASHANTI GOLDFIELDS CORPORATION, LTD.

This Company is the most important in West Africa, and the report of the consulting engineer, W. R. Feldtmann, covers the year ended June 30, 1914. The ramifications of the Company are somewhat of a wide scope, and cover operations at several mines outside prospects, power-plant, and three

MAP OF WEST AFRICAN GOLDFIELDS.

treatment plants. The manager at the mines is John Swan Watkins. The native labor situation was good, and owing to the cocoa industry being somewhat depressed, there is a surplus of natives available.

Prospecting and development work amounted to 18,278 ft., at a cost of £55,493, or $14.50 per foot. Ore reserves are as follows:

Mine.	Tons.	Assay value.
Ashanti main workings	34,100	$21.08
Ashanti Obuasi shoot	213,400	27.30
Ayeinm	120,000	10.00
Justice's	65,000	11.00
Total and average	432,500	$19.56

This is an increase of 67,200 tons. The gross value is £1,797,000, of which there would be £653,100 profit.

The Central treatment plant, using roasting and direct cyanidation, dealt with 97,293 tons of ore yielding $20 per ton, with 93.2% extraction. The Côte d'Or filter-press plant treated 16,915 tons yielding $9.40 per ton, with 80.1% recovery. The Côte d'Or plant also treated 15,501 tons of tailing giving $2.70 per ton.

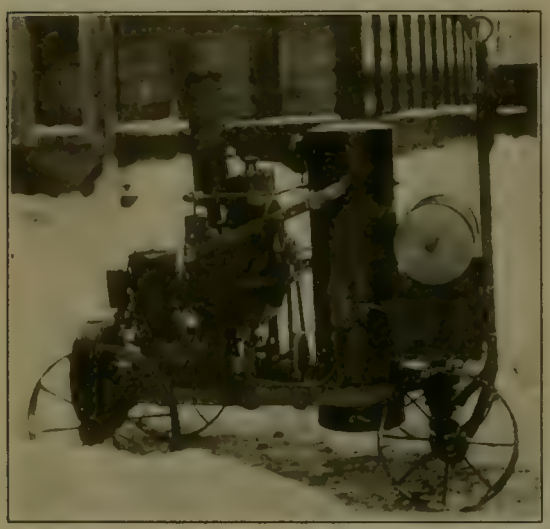
Revenue for the year totaled £441,653, of which £145,731 was profit. The balance of £63,809 from 1912-13 made £209,540 available, of which £147,327 was paid in dividends, making £1,245,864 to date. Construction and equipment expenditure was £30,040.

New Machines and Devices

A Small Portable Air-Compressor

The small gasoline engine driven air-compressor shown in the accompanying illustration has recently been placed on the market by the Ingersoll-Rand Co., of New York. This small compressor has been designed to meet the requirements of small operations and those of a temporary character where air tools of various types are used. The compressor has been found particularly adapted to rock cutting, calking joints, drilling, riveting, tamping, and other purposes. As is well known, compressed air tools have proved their merit on this class of work, and have effected a saving of time and labor over hand methods.

The compressor being portable and self-contained, is well



Portable Compressor

adapted to this work. It is operated by a single-cylinder gasoline engine which is coupled directly to the compressor, both pistons working on the same crank-shaft. The engine is of the single-action two-cycle type. The air-compressor is one of the Company's standard types, known as 'Imperial XII,' has a capacity of 45 cu. ft. per minute at a pressure of 90 lb. Cooling is provided for by a gear-driven pump and an automobile type radiator with large tank capacity, serving both the compressor and engine. The radiator is assisted by a large fan.

The frame, axles, and wheels are of steel and the front axle is arranged with a swivel connection to the frame, permitting horizontal rotation for turning corners and sufficient vertical movement to accommodate the wheels to the inequalities in the road without strain on the frame. An air receiver tested to 300 lb. water pressure and fitted with safety valve and pressure gage is at one end of the frame. The equipment also includes a gasoline tank of 15-gal. capacity which is supported on a large tool-box. The complete outfit weighs 1500 lb. and is designed for transportation by hand, but can be fitted with tongue and singletree if desired. The compactness of the plant is evidenced by the accompanying illustration.

Commercial Paragraphs

Wood Drill Works, Paterson, N. J., has issued an interesting folder entitled 'Talks by the Drill Master.' Told in narrative form, the old driller relates the story of his experience with Wood rock drills.

A. M. Byers Co., Pittsburgh, Pa., has for distribution a circular entitled 'Meeting the Mine Owner's Demands,' which is devoted to the application of wrought iron pipe to the severe usage of mining operations.

The Denver Fire Clay Co., Denver, Colo., in Bulletin No. 50 discusses the Case muffle type oil-fired assay furnace. The bulletin shows two views of the battery of muffle furnaces in operation at the property of the Consolidated Mining & Smelting Co., of Canada.

The Lunkenheimer Co., Cincinnati, Ohio, is distributing two booklets devoted to 'Ferrenewo' and 'Clip' valves. The 'Ferrenewo' valve is made in globe, angle, and cross patterns, all parts of which are replaceable. The 'Clip' type of gate valve has been manufactured by the Company for a number of years.

C. L. Berger & Sons, Boston, Mass., general catalogue of engineering, surveying, and mining instruments is one of the most complete that has been brought to our attention. Published in book form, this catalogue is complete in every detail, replete with illustrations and containing a large amount of data on the subject of surveying instruments and their application.

The Dodge Manufacturing Co., Mishawaka, Ind., through its New York branch, has received an order from the Alaska Gastineau Mining Co., Seattle, Wash., for 20 sets of special floor stands and worm-geared shafts complete. An order has also been received from the Inspiration Consolidated Copper Co. for $7300 worth of equipment covering shafting and about 25 split clutches for the crushing plant.

The Johns-Manville Co. is the manufacturer of J-M asbestos-sponge felted pipe covering, a product made up of laminations of felt composed of asbestos and finely ground sponge. The materials being naturally cellular, they form the basis of the claim that this covering confines more dead air cells than any other covering and therefore possesses higher heat-insulating value. The Company has recently contracted to equip the high-pressure pipes in the new Utah state capitol with this material.

The Western Electric Co., New York, begins the new year by distributing the first edition of its 1915 Electrical Supply Year Book. This catalogue is a marked departure from the regular publicity literature in the electrical supply field. In place of the manufacturer's list prices which catalogues of this kind have usually carried in the past, this new book announces a complete series of Western Electric list prices upon which a uniform basic discount applies, such a discount indicating to the holder of the catalogue his approximate price on all of the articles listed. Although containing over 1200 pages besides an alphabetical index, it probably weighs less than any general catalogue of this nature which has heretofore been issued. One feature of the book is an advertising bulletin embracing examples of advertising and selling helps which the Company furnishes to its agents in connection with the sale of goods manufactured by the Western Electric Company.

WE CAN NOW WRITE UNLIMITED

Compensation Insurance

ON MINES FOR

$3.00

Per $100.00 of Payroll

FRASER & MITCHELL

(Compensation Insurance Brokers)

315-17 FIRST NATIONAL BANK BLDG.
SAN FRANCISCO

Sutter 2420

(SEE REVERSE OF THIS SHEET)

¶ Ever since the present compensation law has been in force the mine owners of California have been forced to pay exorbitant rates for compensation insurance.

¶ By special arrangement with a prominent casualty insurance company the mine owners of the State of California can obtain special rates for compensation insurance through our efforts in collecting the data necessary to show the hazard as it actually exists in the metal mining industry in California.

¶ We have been engaged in this work during the past eight months and are glad to announce our success in quoting the following rates for unlimited compensation insurance complete in every detail:

	Per $100 of payroll.
All kinds of metal mining (underground),	$3.00
Ore milling, smelting and reduction,	1.85
Dredging,	3.00
Commissary department (cooks, etc.),	.98
Office employees (not exposed to operative hazard),	.08

Other surface employees to be rated in accordance with the hazard.

¶ Coverage can be furnished at a moment's notice. Requests for information will be given our immediate attention.

BUCYRUS PLACER DREDGE MACHINERY

2½-foot Gasoline Driven Placer Dredge, Designed to Dig 15 Feet
Shovel Creek Dredging Co., Shovel Creek, Alaska

We have built the machinery for over one hundred placer dredges—from 2½ foot to 16 foot capacities, operated by oil, electricity and steam—more than any other concern in America—heavy, powerful dredges for California conditions and durable light dredges for conditions where strength and light weight are essential—all wearing parts are made of the famous Bucyrus YZ steel, of unequaled strength and wearing qualities—our design and our material are based upon AN EXPERIENCE AS OLD AS THE INDUSTRY.

General Metallurgy

By the same Author.

909 pages, 6x9, fully illustrated, $6.00 (25s) net, postpaid.

From its first publication "General Metallurgy" has been recognized not only as the standard work on fundamentals and general practice, but as an epoch-making treatise.

There's little to add to this:

Engineering and Mining Journal in review of "Metallurgy of Copper," October 17, 1914:

"The magnitude of his task excites our wonder. His execution of it elicits our admiration. Here we are having such an exhibition as Bruno Kerl and John Percy gave us half a century ago, and more recently Carl Schnabel. It was high time that another metallurgical giant should have essayed the task. None but a giant could do anything of this sort.

"No other single treatise, not excepting the classics of Dr. Peters, covered the entire ground. Professor Hofman does it, and does it admirably. His product is satisfying. It is as nearly up-to-date as any such work can be, it is painstakingly accurate, and it is adequate in its presentation of details.

"As to the last point, a noteworthy feature is the copiousness of the footnotes. What an enormous research do they exhibit. In this we are reminded of Kerl's famous Grundriss der Metallhuttenkunde, but that classic covered all the fields of metallurgy and apart from the footnotes the text was necessarily slender. In Prof. Hofman's fat volume devoted to a single metal there could be an amplitude of text, and for those who desire minute study there are the footnotes to take them back to the original authorities. Praise of Prof. Hofman's treatise on copper is as unnecessary as it would be to try to gild burnished gold. The appreciation of the metallurgical profession will come to him."

Metallurgy of Copper

By H. O. HOFMAN, E.M., Met.E., Ph.D., Professor of Metallurgy, Massachusetts Institute of Technology.

556 pages, 6x9, 548 illustrations, $5.00 (21s.) net, postpaid.

This second volume in the Metallurgical Series by Prof. Hofman is the first modern book to cover the whole subject of copper. It gives physical and chemical facts, alloys and compounds, and covers fully the details of modern practice throughout the world.

CONTENTS:

I. Introduction.
II. Properties of Copper.
III. Copper of Commerce, Its Impurities and Their Effects.
IV. Industrial Alloys.
V. Copper Compounds.
VI. Copper Ores: Their Metallurgical Treatment.
VII. Smelting of Copper.
A. Smelting Copper Sulphide Ore.
1. Roasting.
2. Smelting in the Blast Furnace.
3. Smelting in the Reverberatory Furnace.
4. Smelting in the Converter.
VII. Smelting of Copper—Con.
A. Smelting, etc.—Con.
5. The Sulphide Smelting Plant.
B. Smelting Oxide Copper Ores.
C. Smelting Native Copper Ores.
D. Fire-Refining of Impure Copper.
VIII. Leaching of Copper.
A. Leaching of Copper Ores.
B. Leaching Copper Matte.
C. Leaching Metallic Copper.
IX. Electrolysis of Copper.
A. Multiple System.
B. Series System.
C. Multiple versus Series System.

SCHOOLS AND COLLEGES

A. VAN DER NAILLEN SCHOOL 51st and Telegraph Avenue Oakland, Cal.
Established in 1867.
12 months course in **PRACTICAL ENGINEERING.**
Mining, Mechanical, Civil or Electrical.
Send for catalogue.

HEALD'S SCHOOL OF MINES Estab. 1863.
Van Ness Ave. and Post St., San Francisco.
PRACTICAL TWO YEAR COURSE IN MINING.
Special work may be taken in Assaying, Cyaniding, Metallurgy, Drafting, Surveying and General Engineering.
For information address C. E. HEALD, Asst. Supt.

COLORADO SCHOOL OF MINES Established 1874.
Ideally located in the heart of the Rocky Mountains.
Complete courses in Mining, Metallurgy, and Geology.
For catalog and information address
WM. G. HALDANE, Golden, Colo.

MISSOURI SCHOOL OF MINES
A department of the University of Missouri. Established in 1871. Four-year courses in Mining, Engineering, Metallurgy, Civil Engineering, General Science.
Address: Missouri School of Mines, Rolla, Missouri.

MICHIGAN COLLEGE OF MINES
Located in the Lake Superior mining district. Mines and mills accessible for college work. For Year Book and Booklet of Views, address President or Secretary, Houghton, Michigan.

UNIVERSITY OF WASHINGTON
College of Mines, Seattle, Washington.
Coal and Metal Mining, Ore Dressing, Metallurgy.
Special Courses for Mining Men, January to April.

Recent Copper Smelting

Edited by THOMAS T. READ

459 pages 6x9 in. 102 Illustrations Cloth $2.50 postpaid

THE articles which make up this volume have, with some exceptions, appeared in the pages of the *Mining and Scientific Press* during the past four years. Several of the more important papers on copper smelting read before the American Institute of Mining Engineers have been reprinted. The classic papers by John Hollway on 'Using Sulphide as Fuel in Smelting' and by Lewis T. Wright on 'Pyrite Smelting Without Coke' have been included, and an excellent account of smelting at Cananea has been written especially for this book by A. C. Cole.

Few branches of metallurgy have been more in ferment in recent years than copper smelting, and few have made greater progress. In this book the progress and present status of the art are summarized by the men who have been doing the work. It is the best statement of present-day practice available.

THE representative engineers of the mining profession use these pages to keep their names and correct addresses before the public. It is the most effective means of obtaining publicity among metal miners and metallurgists and a dignified medium for the use of Engineers and Assayers.

Put your your name among those of the leaders.

The Third of the Cyanide Series

Cyanide Practice
1910-1913

Edited by
M. W. von BERNEWITZ

Formerly with the Associated and Associated Northern Blocks Mines, Kalgoorlie, Western Australia, and now assistant editor of the MINING AND SCIENTIFIC PRESS, *San Francisco.*

732 pages. 6x9 in. 140 illustrations. Cloth $3.00 postpaid

The leading articles upon current cyanide practice which appeared in the MINING AND SCIENTIFIC PRESS during the period from July, 1910, to January, 1913, have been reprinted in this volume. It contains 205 articles under 156 titles.

Read These Reviews

For the man who desires to keep up on progress in cyanidation, this is one of the books which he should have.—*Salt Lake Mining Review.*

The names of the contributors alone is a sufficient guarantee that the articles are worthy of preservation in a collected form.—*Mining and Engineering Review.*

The intelligent metallurgist will find the present work informative and stimulative. * * * The work is necessary for millmen, teachers, and students. Every reader will gain something new from it.—*Australian Mining Standard.*

On opening the volume one is at once struck with the wonderful scope covered by it, and not only is a full descriptive account of the cyanide practice in vogue in all the leading mines of the world given, but every detail of crushing, milling, roasting, filter-pressing, and cyaniding is fully described, together with a full description of the plants in use. The work is so comprehensive that it is a veritable encyclopedia of ore treatment, and a copy should be in the hands of everyone connected with mining or who takes an interest in that fascinating subject.—*Kalgoorlie Miner.*

WIRE ROPE EFFICIENCY

Careful study of wire rope working conditions and long experience in combining material and construction, have resulted in our being prepared to furnish wire rope for any service that will give maximum results.

For heavy duty of all kinds, we recommend our red strand

HERCULES WIRE ROPE

(Trade Mark Registered)

This grade of rope has great strength, together with unusual toughness and flexibility. It is strong, safe and durable.

All of our ropes are made from highest quality material of the grade best adapted to a particular work.

THEY'RE MADE TO MEASURE

Putman Boots & Shoes

Go on like a glove and fit all over.

Putman Boots are the oldest and best known boots for Civil and Mining Engineers. They are sold all over the world and have justly earned the slogan "The World's Standard." Made-to-measure, water proofed or not, any weight of uppers or soles, all heights, a variety of styles and prices that you will find satisfactory.

Made-to-Measure Shoes

Putman Shoes have a perfect fit, the best of everything in quality, style that is "up-to-the-minute" and that custom-made-individuality so much sought in all wearing apparel. Lace, Button or Oxford styles. Black and all the popular shades of Tan Leathers. Everything from the lightest Vici Kid to Heavy English "Hiking" Shoes.

Our FREE CATALOGUE is sent upon request. It is different from any other and will interest you. Self measurement blanks and full instructions free

Taylor Spiral Riveted Pipe

346 Pounds Pressure

Incaoro Mines, near LaPaz, Bolivia, S. A.

"The handling of all this material was particularly severe, as it had to be transferred twice at New York, several times at the Isthmus of Panama, again at Mollendo, and many times more during the inland journey, ending with a haul of 120 miles on the backs of mules. In all, there were more than twenty transfers of each shipment, yet the material was so well packed, and was itself so substantial (particularly the **Forged Steel Flanges**), that there was no loss by breakage.

"Your pipe and your promptness in shipping, I can only say affords a great favor to anyone in a distant country, and I cannot recommend it too highly.

"Very truly yours,

"(Signed) D. C. BRICKER, Gen. Mgr.,

SCIENTIFIC PRESS PATENTS PATENT AGENCY
911 Crocker Building, San Francisco
Established 1860

PATENTS OBTAINED IN ALL COUNTRIES

We will mail without charge, on request, our Handbook on Patents, Trademarks, and Copyrights, containing over 100 cuts of mechanical movements.

Among the patents recently obtained through us, the following are worthy of special mention:

1,116,235.—VEHICLE BRAKE. Charles H. Brown. It is the object of this invention to provide a brake which is particularly adapted for use on automobiles and other road vehicles, and which is so constructed as to operate directly on the roadbed to retard the movements of the vehicle to which it is attached.

1,116,312.—PARACHUTE ATTACHMENT FOR AEROPLANES. Julius H. Medveczky. It is the object of this invention to provide a parachute attachment for aeroplanes which is so constructed and arranged as to automatically open when the aeroplane is accidentally tipped to an abnormal angle, and which will serve to right the aeroplane and prevent its falling at a dangerous speed in event of disability.

1,115,832.—MITER-BOX. William E. Kawalle. The object of the invention is to provide a simple, reliable, easily adjusted miter-box which is so constructed that the molding supporting angle-plates will move in unison, one with the other, to the extent of at least 45° on either side of a straight line.

1,116,325.—CARBURETER. George W. Ponarouse. The object of the present invention is to provide a simple, cheaply-manufactured easily-operated carbureter which is compact in construction and automatic in operation.

(Copies of any of the above furnished for 10 cents each)

POWER PLANT EQUIPMENT BARGAINS

Owing to purchase of power from Transmission Lines, we can offer some special low prices on steam equipment now being discontinued in one of our best equipped Coal Mines in the Northwest.

2—250 K.W. Ridgway 500-volt D. C. Generators, direct connected to 18"x20" Ridgway Engines.

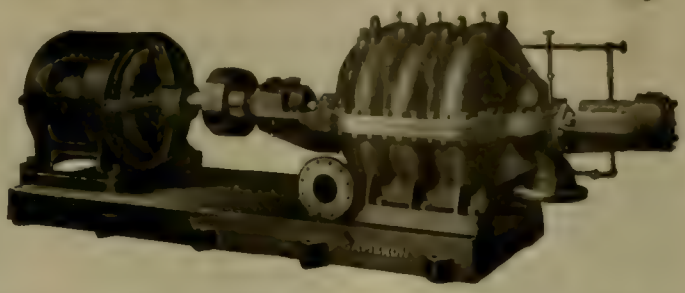
The Slogan of the Cameron—"Character: The Grandest Thing"



1000 Gallons Per Minute Against 500 Feet Head

The **Cameron Centrifugal Pump** (illustrated) is a motor-driven 6″ four-stage, with a capacity of 1000 gallons a minute against 500 feet head at 1165 R.P.M., and has proved very efficient and economical.

Mining engineers have found the Cameron Centrifugal to be the best for the long, steady pulls of pumping so prevalent in mine work.

It is very simple, compact, and strong. The casing is horizontally split, so that the working parts may be easily reached without disturbing pipe connections or pump alignment. Finest material and workmanship.

Built in many types and sizes for various classes of work. Our Engineering Department will gladly figure on your requirements.

Write for Bulletin No. 151 giving detailed information about our Multi-stage Centrifugal Pumps.

A. S. CAMERON STEAM PUMP WORKS

11 Broadway, New York **Offices the World Over**

Concentrating Ores by
FLOTATION

BY

THEODORE J. HOOVER

Second Edition. 261 pages. 60 figures. Cloth, 6x9 in., $3.75 postpaid.

This is a practical working guide. It contains detailed descriptions and working drawings. The history of the experimental work which has led up to the present state of the art is summarized, as is also the litigation between patentees. The theory of flotation is discussed and the methods for testing the applicability of the process are stated. Full descriptions are given of the many processes that have been introduced or proposed. One chapter discusses the economies of flotation, while a complete bibliography makes the volume invaluable to those engaged in further experimental work. In short, Mr. Hoover has given all that any ordinary engineer will need or care to know about flotation.

Contemporary with many of the most illustrious masters of Art, Literature and Navigation of the middle ages, Agricola was the conspicuous authority of his time on Mining and will ever be remembered for his great work on the subject. A classic which will endure—

DE RE METALLICA

Confident that there are still many who have not seen the First English translation, and who would like to know more of this valuable volume, for them we have issued a brochure of 32 pages, entitled "The book that made Agricola famous." Sufficient of the illustrations are reproduced to give an excellent impression of how able and advanced the miners of the XVI century were. Sent free.

HOW—WHY—WHERE

That's what our new Catalog No. 7 tells you.

How the Lane Mill does its work.

Why the product is superior, the cost of operation low, and the extraction high.

Where they are operated, and what kind of work they are doing.

It also tells the method of operating with stamps; how they are sectionalized for mule packing; about their adaptability for the treatment of different kinds of ores; and gives other information which will interest you.

Send for this Catalog No. 7. Do it now.

No. 5 BLASTING MACHINE

SAVE

TIME AND MONEY

BY USING

DU PONT

Blasting Machines

EVERY day more blasting is being done with electrical blasting machines.

WHY?

Because several bore holes can be fired at one operation. Such action dislodges more material than many single shots.

Less drilling and loading is necessary when electrical blasting replaces single-shot methods.

Put this new improved, powerful, strongly made No. 5 Blasting Machine to work. It's a time and money saver, and lessens blasting accidents.

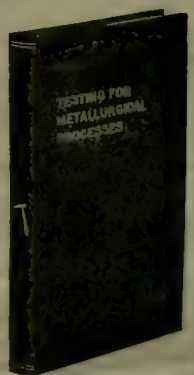
Testing for Metallurgical Processes

By JAMES A. BARR

216 Pages—Illustrated—Indexed—$2 Postpaid

THIS BOOK is designed to assist in the selection of the process of treatment for any ore. The author describes the apparatus employed in making laboratory and small-lot tests. It is founded upon experimental work at the Michigan College of Mines, and the methods recommended have been tested in practice. It is brief and practical, equally valuable to the student and the practicing engineer



PUBLISHED AND FOR SALE BY

MINING PRESS, 420 Market Street, San Francisco, California

THE MINING MAGAZINE, Salisbury House, LONDON, E. C.

A well known California dredge is operated by current supplied by Pelton-Francis turbine unit shown above. Remarkable results have been attained with this installation. The service is severe, hydraulic conditions unusual and labor costs high. In spite of these handicaps, operating costs are low. The report of the superintendent is unusually interesting. Would you like a copy?

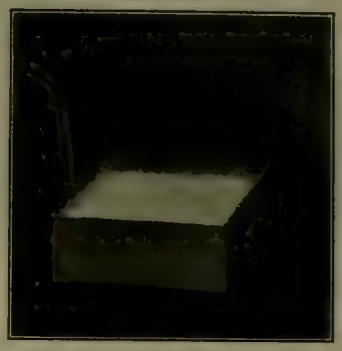
PERMANENCE



Until **FILTROS** was perfected—until this new, white, porous, silica filtering medium was developed there were always to be taken into account

The expense of materials replaced;
The labor required for replacement;
The production loss due to idle equipment.

FILTROS is changing all this. **FILTROS** plates represent equipment as permanent as the concrete foundations under your machinery.

If that were all it would be enough to recommend **FILTROS** on the ground of economy.

But that is not all. The uniform porosity of **FILTROS**, its resistance to chemicals and high heats and its strength lend themselves **in the degree of perfection** to an increased production capacity not to be ignored by the Mine Manager, who justifies measures by results.

Write for the **FILTROS** booklet.

MINE SAMPLING AND VALUING

By C. S. HERZIG

with a chapter on

SAMPLING PLACER DEPOSITS

By CHESTER WELLS PURINGTON

163 Pages 6x9 Illustrated Cloth $2 Postpaid

This is the first comprehensive treatise on a most important part of the mining engineer's work. It presents a complete logical and well-rounded discussion of the principles and practice of sampling and valuing mines. Most experienced engineers will be glad to have such a volume in their library, and to the young engineer, who has not been through the mill, it should prove well nigh invaluable.

American Steel & Wire Company's

Trenton-Bleichert System

Aerial Tramways

We are the sole licensees in America of this type of construction. Every detail has been thoroughly worked out and we put into these constructions only material of the most approved and substantial kind including

American Wire Rope

NO matter what the contour of the ground, we will construct a tramway that will transfer material in a bee-line at minimum expense, and no grades are too steep to surmount; no rivers or valleys too wide to cross; and no grading, bridges, or viaducts of any kind are required. There is practically no limit to the length of these tramways. We have one line carrying ore twenty-one miles.

Write for our complete descriptive book showing every form of application. And we will be glad to work upon propositions submitted to us, returning full and complete specifications and costs of construction.

The SAFE Brake Lining

The safety of your men and the efficiency of your machinery depend to a great extent upon the effectiveness of your brakes. A charred brake lining or one that slips may give way at a critical moment, and injury to men and machinery may result.

J-M ASBESTOS BRAKE BLOCKS

cannot burn or char. Made of pure long-fibred asbestos and fireproof binding cement moulded under enormous pressure. You can throw on the brakes as hard and as long as you wish with no danger of the lining catching fire. It is absolutely proof against any degree of frictional heat. Oil, water, acids or grit will not harm it. This lining is ideally adapted for brakes on mining hoists, pile drivers, derricks, excavators, dredges, etc. Made for service other linings will not stand.

Write our nearest branch for sample and "J-M Asbestos Brake Blocks Booklet."

Placer Dredges

We are Builders of Complete Dredging Machinery Outfits, for either Placer, River or Harbor Dredges, of all Types. We also specialize in General Dredge Repairs.

Let us figure with you when you are in the market for a Dredge or General Repairs.

SEATTLE MACHINE WORKS

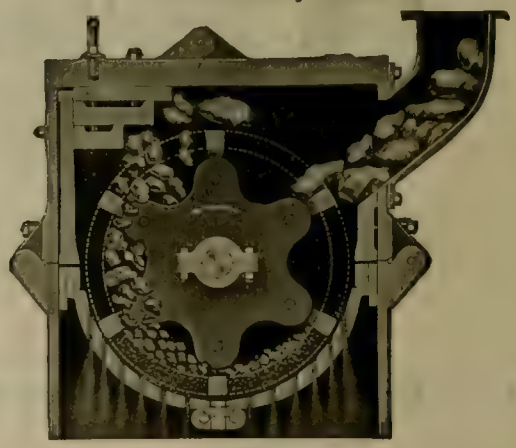
INCORPORATED

37-51 W. LANDER STREET

SEATTLE, - WASH.

Gardner Crusher and Pulverizer

For Laboratory Work



This Crusher is adapted for grinding any material, wet or dry, to any desired degree of fineness, ranging from 2½" to 20-mesh and under.

For laboratory work it is especially desirable. The hopper can be closed so that nothing will be lost and it is built exactly like the larger machine, with necessary changes for laboratory use. Small power required. Easily cleaned and always reliable. Send for catalogue giving full information.

C. O. BARTLETT & SNOW CO.

Cleveland, Ohio

WE HAVE MADE A

"Trouble-Proof" Carbide Lamp

For the Metal Mine

THE

JUSTRITE

No parts can be lost or knocked off. Clogging is impossible. Ordinary care will keep it clean. It is the simplest thing imaginable to adjust the flame just right. And no matches are needed—it is self-lighting.

These points are important to you because they mean that you can buy a practical, fool-proof lamp that will give you in full the savings and efficiencies of carbide lighting. Lamps for every mine condition.

Write for Special Bulletins on Metal Mine Lighting.

JUSTRITE MFG. CO.

546 W. Van Buren St., Chicago, Ill.

Western Special — No. 105

—Lamps for Every Metal Mine Requirement—

20 Styles to Select From

No. 91—"Half Shift." Burns 4½ hours on one charge. No matches required. Steady flame. No clogging. Candlestick attachment. $1.50 each.

No. 93—"Anaconda Special." Similar to No 91, but stronger. Burns 5 hours. Made with candlestick attachment and steel hook $2.00 each.

No. 50—"Jumbo." Burns 6 hours. Seamless aluminum. Made for exceptional long service. An unusually efficient and durable lamp. $3.50 each.

No. 83—"Arizona Special." Burns 5 hours. Similar to No. 93. Has Fishtail burner giving strong, upright flame. Bail and swivel hook attachment. $2.00 each.

No. 105—"Western Special." Burns 5 hours. For superintendents, engineers, inspectors, etc. Same size as No. 83 with large handle. $2.00 each.

Keeping Everlastingly At It

Working dependably, day in, day out. Rarely if ever stopping for repairs. Increasing its cutting capacity with age.

Wood Rock Drill

THE DRILL WITH THE VANADIUM TUNGSTEN IRON CYLINDER, CHEST AND AIR HEAD

Vanadium makes the iron finer in grain and combines with the tungsten to make it much tougher. The result is a metal that cannot crystallize under vibration nor crack under hard usage. The fine grain assumes in use a silver-like surface that will not wear appreciably for many years nor cause friction.

This is one of the vital reasons why Wood Rock Drills keep "everlastingly at it" and give you the kind of service and results you want. Write for Catalog and details of our "guaranteed for life" policy.

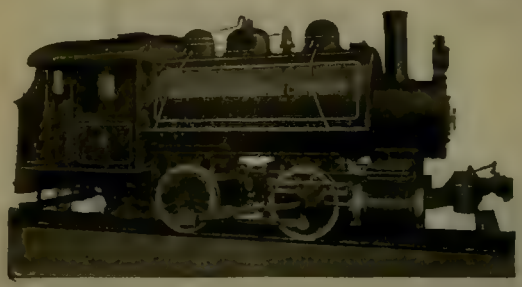
Contractors' Locomotives



Length of service, proportion of time ready for use, and work performed determine the value of a locomotive.

With these points in mind we have designed, and build our small locomotives to insure reliability and constant service. Only tested materials are used, and all wearing parts are made to templates and gauges. With this method all wearing parts are absolutely interchangeable on locomotives of the same size and design, and long delays waiting for duplicate parts are avoided. Duplicate parts are kept in stock for immediate shipment.

A CHANCE TO ECONOMIZE

A FEW OF THE MANY BARGAINS IN SLIGHTLY USED AND REBUILT MACHINERY READY FOR SHIPMENT.

The machines listed below are guaranteed and offered at prices which will interest you

COMPRESSORS
1—400-ft. Sullivan 2-stage belt-driven compressor (NEW)
1—12"x16" Giant compressor
1—10"x12" Ingersoll compressor
1—6"x6" Nagle Corliss compressor

AIR DRILLS
4—3 in. Sullivan Hy-Speed drills.
4—2¾ in. Sullivan Hy-Speed drills
1—2½ in. Victor drill.
2—Hardsoog Wonder hammer drills.

STAMP MILLS
1—20 stamp mill, 850 lb. drop
1—10 stamp mill, 1000 lb. drop
1— 5 stamp mill, 1000 lb. drop
1— 2 stamp mill, 1000 lb. drop
1—5-ft. Huntington, latest improved mill
1—6-ft. Beers mill, almost new

ROCK CRUSHERS
1—No. 2 Austin crusher, cmplete
1—No. 0 Gates crusher, almost new
1—No. 2 Dodge crusher
1—No 3 Dodge crusher

STEAM AND GASOLINE HOISTS
1—15 H.P. Fairbanks-Morse gasoline hoist
1—15 H P. Union gasoline hoist
1—10"x14" double cyl., single drum steam hoist
1—8"x8" double cyl., single drum steam hoist
1—6"x8" double cyl., single drum steam hoist

ELECTRIC MACHINERY
1—50 kw. Westinghouse Generator, 2 phase, 220 volts, with switchboard.
1—80 hp. General Electric motor, 3 phase, 440 volts.
1—10 hp. Westinghouse motor, 3 phase, 440 volts.
1—7½ hp. Westinghouse motor, 3 phase, 440 volts.
1—5 hp. General Electric motor, 2 phase, 220 volts.

CONCENTRATORS
3—6-ft. Johnson concentrators
2—No. 4 Wilfley concentrators

WATER WHEELS
1—5-ft. standard Pelton wheel
1—36" standard Pelton wheel
1—36" inclosed case Pelton wheel
1—36" inclosed case Oakland wheel
1—24" inclosed case Oakland wheel
1—12" inclosed case Pelton wheel

PUMPS
1—6" Cornish pump, complete with shaft and gearing
1—No. 9 Cameron sinking pump (NEW)
1—No. 7 Cameron sinking pump
Centrifugal, Power, and Steam Pumps in all sizes.

GASOLINE ENGINES
1—60 hp. Union horizontal engine.
1—50 hp 4 cylinder upright engine.
10 NEW ENGINES from 2 to 18 hp.

ENGINES
1—350 H.P Cross compound Corliss
1—150 H.P. Atlas Corliss (NEW)
1—100 H.P. Bates Corliss, complete

BOILERS
1—150 H.P. B. & W. water tube boiler
1—125 H.P. B. & W. water tube boiler
1— 60 H.P. fire box boiler
1— 35 H.P. fire box boiler

MISCELLANEOUS
1—20"x24" Hendy clean-up barrel
2—Challenge ore feeders
40 sets new steel shoes and dies
Pulleys, Shafting, and Belting.

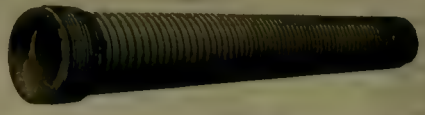
WOODEN TANKS AND PIPE DO NOT RUST.



They have no rivets to rust or wear. Water preserves them and sulphur, mineral water and fumes will not corrode them. Our tanks have a patented feature which keeps them swelled tight. We have three factories close to Redwood or Douglas Fir, and give prompt attention to rush orders. ¶ Our pipe can be laid in shallower ditches and is cheaper than steel. It requires less labor and experience to lay in place than does metal pipe. Its carrying capacity is twenty per cent greater than cast iron pipe.

"Wooden Pipe; Its Many Advantages," goes into this subject in a readable way. Copies of the booklet mailed free.

Simplicity

THE AKINS CLASSIFIER—PATENTED
For Separating Sand from Slime, Washing Granular Products, Dewatering Concentrates, etc.

Early efforts always produce complex means of accomplishing results. Simplicity is attained only after experience has taught the easy way. The short cut, the simple way, often brings with it a superiority in results.

The Akins classifier is the simple way. Look at the illustration—two bearings—a simple rotary motion. The illustration shows its extreme simplicity—widespread use demonstrates its superiority.

Colorado Iron Works Company, Denver, Colo.

B. & B. Tramways Are More Than Just Tramways

They are a wonderful combination of engineering brains and many years of invaluable experience.

They run right because they're built right.

The B. & B. Aerial Tramways are constructed to handle practically every kind of material under every possible working condition—up and down hills, across valleys and rivers.

The rougher the country, the more economical do they invariably prove, in comparison with every kind of surface haulage.

Write us today about the haulage con ditions at your plant. We'll then recommend the kind of B. & B. Tramway that will prove most economical for you, and furnish estimate of cost. This will not cost you a single cent, nor obligate you in any way whatever.

And remember this: B. & B. Tramways positively are not expensive. They cost not one cent more than *just* tramways—the ordinary, every-day kind that are made without B. & B. brains and experience.

The sooner you write and get out Catalog No. 15, the sooner you'll know what a B. & B. Tramway can do for you.

Flotation Concentration

The continuance of patent litigation by the pending appeal to the Supreme Court has, according to the best legal advice, opened way for intervention on behalf of the Elmore Patents, which have not yet been represented in any proceedings in the United States.

Users and intending users of Flotation Processes employing a small quantity of oil or violent agitation can be absolutely protected against litigation and demands for exorbitant royalties by adopting licenses under the Elmore Master Patents. Plants are working on a large seale in various parts of the world under such licenses.

These pioneer patents and established users are of earlier date than the patents of any competitor.

Elmore's English, Australian, and German Patents have already been pronounced by courts as valid and subsisting, and all the prolonged litigation in those countries has been initiated by the owners of the Elmore Patents.

The Ore Concentration Company (1905) Limited

SALISBURY HOUSE, LONDON

USE

"Sirocco"

TRADE MARK

FANS FOR

MINE VENTILATION

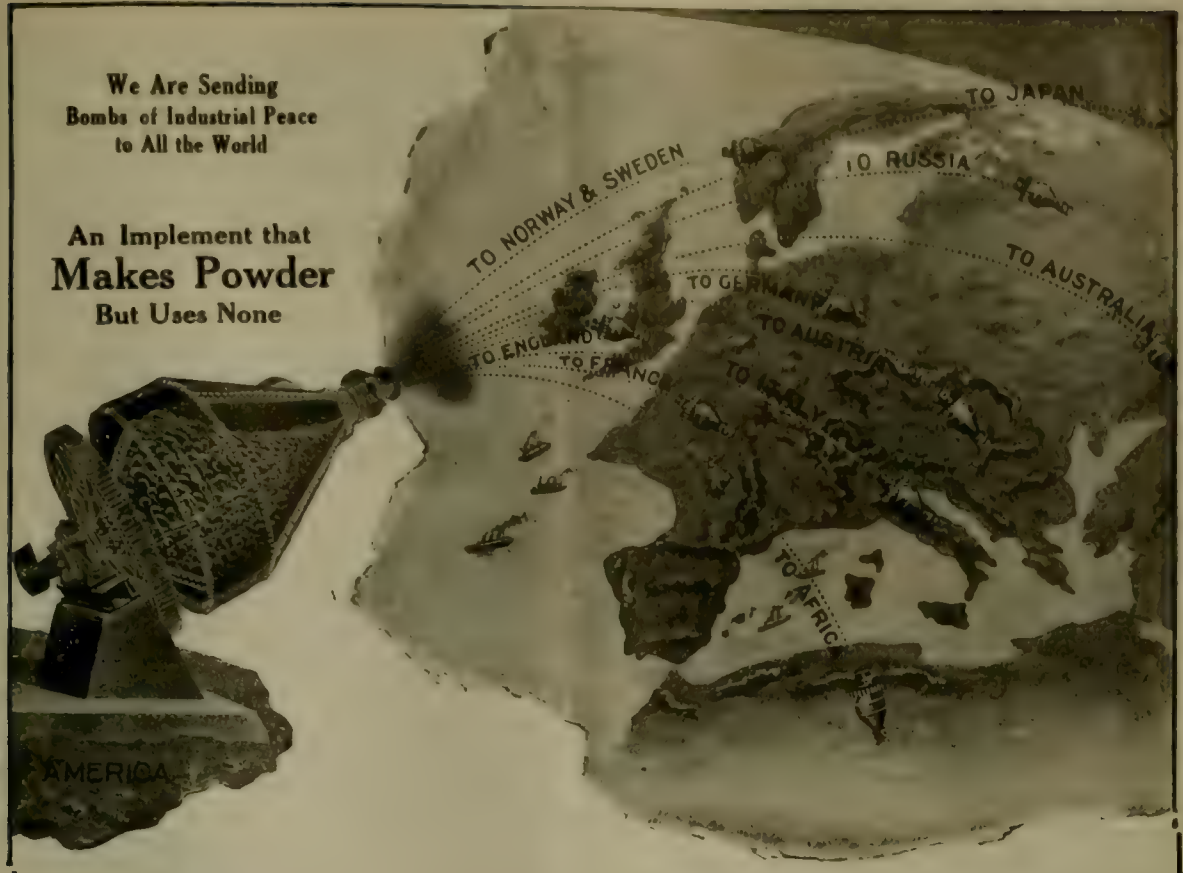
They use a minimum of power.
They require the least space.
They are the least expensive to install.
They are built in enough styles and arrangements that *your* work can be done perfectly and economically.

The "Sirocco" saves power over fans of the paddle wheel type *because* the design makes it possible for every bit of energy consumed to produce the maximum volume of air.

Successful installations of "Sirocco" fans are the best test. The Miami Copper Co. increased the efficiency of their miners about 35%—the same number of men getting one-third as much tonnage again as previously—saving also enough on compressors to not only run the fan but to pay for the fan in a short time.

If you have bad air in your mine, let us tell you about "Sirocco"

The Hendrie & Bolthoff Mfg. & Supply Co.
DENVER, COLO.



HARDINGE MILLS

(Grinding Mortars)

Have found the range of every mining camp on earth. Experience has taught us how to build them and they never fail to reach their target.

Let us know the nature of your object, whether coarse or fine grinding, and we will give you the range and adjust your sights. We have had thirty years' experience behind the metallurgical gun. Our experience is at your disposal without obligation on your part.

ARTICLES

FRIENDLINESS V. FRICTION AT THE BUNKER HILL & SULLIVAN.
By John A. Goodell..... 57

The story of the Industrial Y. M. C. A. at Kellogg, Idaho. This now occupies a two-story, with basement, building, affording reading, recreation, game, and lodge rooms, with gymnasium, swimming pool, bowling alley, and other features. A library and classes are maintained, and large use is made of the club. It is supported in part by membership fees and in part by contributions from the B. H. & S. M. & C. Co., and is felt by the manager, Stanly Easton, to have fully justified the support given it by the Company. Mr. Goodell, who writes the article, is an experienced Y. M. C. A. worker.

GOLD MINING AND MILLING IN THE SOUTHEASTERN STATES.
By W. R. Dodge..... 59

The oldest goldfield in the United States is extensive, and in the opinion of Mr. Dodge, a metallurgical engineer resident within it, worthy of reinvestigation. Placers and wide belts of weathered rock, 'saprolite,' are present, and in them fine gold occurs. The material has been worked by hydraulicking, followed in places by stamp-milling and cyanidation, concentration, or chlorination.

MINERAL PRODUCTION OF THE DUTCH EAST INDIES..... 62

DRAINING KERR LAKE AT COBALT, ONTARIO.
By Ben Hughes..... 63

Pumping the water out of Kerr lake began August 28, 1913, and proved much easier than cleaning the mud off the bottom after the water was gone. This work is now under way, hydraulic giants mounted on a scow, with suitable pumping arrangements, being employed. Eight acres is yet to be cleared. The Kerr Lake and Crown Reserve companies will be able, when the work is completed, to mine from the surface the unexhausted rich upper parts of the veins worked below.

THE ORIGIN OF THE DOLOMITES.
By Francis M. Van Tuyl..... 64

Results of studies in Iowa that lead to the belief that dolomites are formed from limestone by replacement, before the beds emerge from the sea.

RHYTHMIC PRECIPITATION OF FERROUS FERRI-CYANIDE AND FERROUS HYDROXIDE IN JELLY.
By H. J. M. Creighton..... 65

Experiments with silver nitrate solution on gelatin show that in colloids, deposition from solution under the influence of electric currents is rhythmic and produces structures similar to the banding in veins. See also Editorial and Discussion departments.

PROSPECTING WET PLACER GROUND BY SHAFT SINKING.
By Donald Steel..... 66

Contrary to general opinion, it is possible to sample wet placer ground by shafts, if the work be carefully done and the methods adapted to it. Mr. Steel describes a caisson sinking method that he has employed, giving full details and sketches as well as results of a test. An article to cut out and paste in your notebook.

PRESERVATION OF TIMBER IN MINING.
By F. K. R. Moll..... 68

Mr. Moll, who as it happens is now serving in the German army, reviews the needs and methods of wood preservation as applied to mine timbers. He points out that the brush and open tank methods have already been proved to be defective, and describes the methods of impregnation that have been brought to success in Germany and Austria. This article was prepared before the war as a result of Mr. Moll's studies of American conditions and needs, and is designed to prevent repetition of old mistakes.

IMPROVEMENTS AT THE TRAIL SMELTER, BRITISH COLUMBIA.. 74

The Consolidated M. & S. Co. spent $482,000 in improvements in the year that ended September 30 last. The lead and copper plants were extensively overhauled. Two Wedge furnaces and a Cottrell precipitating plant were added.

CHEMICAL PROBLEMS IN GERMANY..... 75

The war has made a shortage of gasoline, rubber, nitre, and jute among other important materials. For the first, alcohol and benzol are being used. By combining acetone and benzol products with caoutchouc regenerated from scrap rubber, a substitute is made, but synthetic rubber is being sought. Substitutes for saltpeter for many uses are possible, but the shortage is severe. Cellulose is used in place of jute.

TEMPORARILY, at least, the new Arizona law requiring that not more than 20 per cent of the labor employed by one person or concern shall be alien, will not be enforced, an injunction having been granted by the United States court pending a test of its constitutionality.

JOPLIN mines closed 1914 with prices at $50 to $52 per ton, as against $37 to $40 the year before. The war abroad has stimulated the American zinc industry, and the producers are enjoying another of the periods of prosperity that fortunately come between the equally characteristic periods of depression in zinc mining.

GOLD production in the United States in 1914 is estimated by the Director of the Mint, to have amounted to 4,490,336 fine ounces, equivalent to $92,823,500, an increase of 190,532 ounces, or $3,939,100, over the output for 1913. California ranked first with 1,037,537 fine ounces; Colorado was second with 961,748; and Alaska third with 766,744. In silver, Nevada led with 14,814,200 fine ounces, Idaho was second with 12,689,500, Utah third with 11,397,000, and the total was 67,929,700. The corresponding figures for 1913 were: Nevada, 16,090,083; Idaho, 9,989,193; Utah, 13,084,835; total, 66,801,500.

ARMOR PLATE manufacture by the government, as proposed by Congress, was discussed at some length in our editorial columns about a year ago. A special committee, consisting of Messrs. B. R. Tillman, and L. P. Padgett, respectively chairmen of the Senate and House Committees on Naval Affairs, and Rear-Admiral Joseph Straus, has now been appointed to make a thorough investigation of the feasibility of the project as a national investment. As about fifty cities are already making an effort to have themselves recognized as the most desirable site for the proposed plant, there is a probability that other arguments than those founded on business principles will be forced upon the attention of the committee.

THE report by a political commission, composed of the State Veterinarian, the Secretary of the State Board of Health, and the State Horticultural Commissioner of California, stating that serious damage is done to farming lands in the vicinity of the Mammoth smelter in Shasta county and the Penn smelter in Calaveras county, will not carry great weight with technical men, though it may be seriously considered in political circles. This commission did not report upon the Selby smelter, though intimating that it, probably, is also a source of damage. It, therefore, does not come into direct conflict with the findings of the Selby Smelter Commission which we recently summarized. We believe that the Selby commission got at the real facts. We are sure that its members investigated the question more thoroughly than any other commission, and it had the great advantage of being composed of technical men selected by agreement of both agriculturists and smelters. The state commission illustrates an excellent way 'not to do it.'

EXPRESS companies, we are pleased to note, have not all ceased to operate as a result of the establishment of the Parcel Post. Delighted as we are at the success of that, the most recent venture of the United States government into business, we have now a special cause for gratitude that the Wells Fargo continues to bring down the products of the mountain countries. With the assistance of that Company, Mr. Arthur Gibson sent the editorial staff, from Sonora, a box of apples fully equal to any we remember in our early boyhood. No country subscriber has yet paid us in the proverbial cabbage, but between Parcel Post and Wells Fargo we have hopes.

PYRITE SMELTING

Early in December, Mr. Robert Sticht gave a talk on this subject before the New York section of the American Institute of Mining Engineers. His address, a valuable contribution to the literature of the development of the art, was notable in many ways, especially for the modesty and frankness with which Mr. Sticht described his own work. According to his analysis the essential factors which led to the success attained in his development of pyrite smelting at Mount Lyell were the fact that the ore there was well suited to the process, and the high regard in which American engineers are held in Tasmania, which led to his being given a free hand to carry out his ideas. As Mr. Sticht aptly remarks, it is much easier to find a process to suit an ore than it is to find an ore to suit a process; nevertheless there can be little doubt that the scientific imagination and practical ability of Mr. Sticht were larger factors in the success attained than he himself is willing to admit. His

remarks on the occasion referred to were so full of dry humor and keen common sense that our readers will doubtless be grateful for a brief summary of the points made.

When Mr. Sticht went out to Mount Lyell in 1895 he had had some experience with attempts at pyrite smelting, for brief periods, in Colorado, and therefore had some foreshadowings of what might be done. He was singlehanded and the property was just beginning to be developed, so there were all the usual pioneer difficulties, especially in transportation, and it was necessary to pioneer in coke-making as well as to develop copper smelting. He was fortunate in having only two substances to deal with; a pure pyrite free from zinc and lead, and a silicious ore containing 70 per cent free silica, the joint alumina content being satisfactorily low. This material all came to the furnaces in coarse form, not over ten per cent of it being finer than half inch. The furnaces built were not large, according to present standards. Those now in use are 54 inches wide and 18 feet long, and the first furnaces were 36 inches by 10½ feet. The height of the smelting column has been increased until it is now 18 feet as a maximum. The early slags were very silicious, the charge consisting of two parts of pyrite to one of silicious ore. Now, from 1.7 to 1.3 parts of pyrite are used to one of silicious ore. The matte first made required resmelting. At first a hot blast was used, but Mr. Sticht soon perceived that if enough air were provided to oxidize the iron it would furnish its own heat, and additional blowing capacity was provided. The open, coarse charge permitted free passage of the air, and by blowing 20,000 cubic feet per minute it was not difficult thoroughly to oxidize the iron, with the resultant production of a good slag, enough heat to keep the furnace going, and a matte of the desired grade. While it was found entirely possible to run the furnaces at Mount Lyell without any coke on the charge, this was not the practice, since it imposed a degree of strained attention on the metallurgist which is beyond the limits of human capacity. In other words, they had at Mount Lyell the same experience metallurgists have had elsewhere; namely, that while it is quite possible to smelt without coke, it is better economy to use it. According to Mr. Sticht, they formerly used 1.1 per cent coke; now they use 3.5 to even 5 per cent; the silicious material which is now being used not containing so much free silica as that formerly used. As Mr. Sticht phrased it, it is cheaper to burn up coke than to burn out the metallurgist and his staff.

The importance of the absence of fine ore on the charge was emphasized by the other metallurgists present. Mr. H. A. Prosser related that when the smelter at Mammoth, California, was started, limited crushing facilities made it necessary to feed the furnace with lumps a foot in diameter, and experience showed that this coarse material was not a detriment, as had been expected. Speaking of the new smelting plant at Anyox, Mr. George A. Guess related that through a failure of the crushing plant it was necessary to feed the furnaces with lumps as large as a suitcase, no detriment resulting. As the charge here contained 20 to 30 per cent of fine ore it is quite possible that, as suggested by Mr. Prosser, the breakdown of the crushing plant was a blessing in disguise. The early difficulties experienced at Anyox were overcome chiefly by making it possible to get more air through the furnace; for, as pointed out by Mr. Lewis T. Wright many years ago, the essential requisite for success in pyrite smelting is to maintain a sufficiently rapid rate of smelting. Mr. R. L. Lloyd made the point in the discussion that an ore which came to the furnace in lumps might still yield 'fines' in smelting, since some sulphides decrepitate on heating. Mr. Guess confirmed this, relating an experience in which a consignment of sulphide ore completely decrepitated into sand inside the furnace, tremendously increasing the resistance to the blast.

A point which did not chance to attract much attention in the discussion, but which is exceedingly important, is that as compared to an ordinary furnace a pyrite furnace is like a runaway horse compared to old Dobbin. The pyrite furnace must be given its head; it indicates the conditions under which it will run, and must be allowed to have its own way. If enough iron and sulphur are present to yield the heat required and the charge is sufficiently porous so enough air can be blown through to generate the heat rapidly enough, the pyrite furnace will generally run without too much difficulty. The presence of alumina in the charge introduces a difficulty, for the reaction when it unites with the silica is endothermic. Worst of all is the joint presence of alumina and magnesia, since these may unite in the slag to form the spinel molecule, which is almost infusible at blast-furnace temperatures. It is surprising what profound effects apparently minor differences make in this regard. At one of the Russian copper smelters a barren quartz containing 96 per cent SiO_2 is hauled some miles for use in the furnace. Several times during the absence of the consulting engineer, Mr. W. G. Perkins, the local managers have tried to economize by using an equally good looking rock, containing 89 per cent SiO_2, which occurs near the furnace. Always capacity fell and coke consumption rose, and when inquiries came from the London office, the superintendent has had to admit that the substitution had been made. Perhaps the most striking example of the necessity for favorable chemical conditions in the charge is the smelter at Copper Cliff, Ontario, where an ore which is high enough in sulphur and iron to smelt pyritically has defied the persistent efforts of some of the best metallurgists of the day to make it run pyritically. The situation at this plant is such a puzzling one that we shall reserve its detailed discussion for a subsequent editorial. For the present we may conclude by emphasizing the chief point made by Mr. Sticht: namely, that the first essential for success in pyrite smelting is to have an ore which is suited to the process; and by reiterating our own point, that the physical character of this charge must be such as to permit blowing sufficient air through it to smelt at the speed which must be maintained.

BANDING IN ORE DEPOSITS

Banded structures, so commonly observed in veins, have always been a source of interest to geologists, and long ago Posepny devised the term 'crustification' to describe such structures, which he rightly considered an infallible indication of deposition from solution. The term reflected the general view of geologists, then and since, that such structures must necessarily have been produced by variations in the composition in the solutions traversing the fissure, one solution having deposited a 'crust' of a given composition, only to be succeeded by a solution of different composition which deposited a 'crust' of markedly different character. There are several difficulties involved in this explanation. The transition from one crust to another is usually distinct and abrupt, but it is hard to imagine how similarly abrupt changes could take place in the composition of the solutions, for even if one source of supply were suddenly shut off and another took its place it must be expected that a certain amount of mixing would take place while the first solution was being expelled by the second, and therefore a transition layer should occur. More difficult to explain is the alternation of bands, for which a rhythmic alternation of solutions must be presupposed, an assumption that severely taxes our credulity. Thus in the veins of the Reese River district of Nevada well developed bands of ruby silver ores occur alternating with bands of quartz. It is decidedly hard to comprehend how solutions carrying the silver minerals in solution can have been caused to alternate with solutions carrying only silica.

The tremendous amount of work which has been done on colloids of recent years has gradually led up to another and more plausible explanation. The nature of this is clearly indicated by the brief article by Mr. H. J. M. Creighton, published elsewhere in this issue, in which is described a simple experiment by which alternating bands of precipitates are produced in colloidal substances by rhythmic precipitation under the influence of an electric current. The colloidal character of freshly precipitated SiO_2 is well known. Assuming a vein filled with such a colloidal mass, containing small quantities of other substances, it is not difficult to imagine that the combined effect of the ground-water circulation and terrestrial currents would produce alternating bands of precipitated minerals and barren quartz. In addition to overcoming the difficulties already mentioned, another not referred to at once disappears. According to the theory of crustification two bands, one on each side of the supposedly open fissure, are produced, and the vein must necessarily exhibit an even number of bands. But this is not always the case, and no very plausible explanation has been offered. The suggested method renders any explanation unnecessary, since the bands would then be produced one at a time. If the new theory is a valid one, it is no longer necessary to assume the long persistence of open fissures to great depth, since a fissure might be filled with colloid SiO_2 in a brief space of time, while its subsequent conversion into a banded vein might extend over a long period.

Not the least interesting aspect of such a theory is that it reconciles the divergent views of the 'ascensionists' and 'lateral secretionists.' The first filling of the fissure might be brought about by the forcing in from below, perhaps under considerable pressure, and in a semi-consolidated state, of colloid SiO, which may be regarded as the final *liquidous* phase of the consolidation of an igneous magma. But banding whenever found, is commonly parallel to the axis of the fissure, and therefore must be the result of the action of a solution, presumably the circulating ground-water attempting to cross the vein from one side to the other. Such a theory of banding is in many ways a suggestive one, and seems well worth the attention and discussion of geologists. A good deal of work has already been done along these lines. More than twenty years ago Mr. G. F. Becker suggested that the wall rocks of veins might act as semi-permeable membranes. Not long after Mr. R. E. Liesegang discovered the effect of placing a drop of silver nitrate solution on a layer of gelatin, referred to by Mr. Creighton, and out of the suggestive line of thought thus evoked has grown the work of such investigations as Messrs. Hatschek and Simon, and Morse and Pierce. The matter was discussed at some length by Mr. Liesegang in his volume 'Geologische Diffusionen' published last year, but it seems to have attracted comparatively little attention in this country, much less than its apparent importance would seem to deserve.

ADIRONDACK GOLD DEPOSITS AGAIN

In his study of the French Revolution, Thomas Carlyle frequently repeats the assertion that anything which is not founded on truth cannot long prevail. The belief is a comforting one, but unfortunately experience in the field of mining seems to indicate that this rule, as many others, is subject to exceptions. The delusions that gold can be profitably extracted from sea water, and that it exists in ores in forms in which it cannot be detected by ordinary fire assay, have, for example, shown a vitality which is quite out of keeping with their lack of fundamental truth, and survive repeated demonstrations of their fallacy. A less well known but equally hardy belief is that the sand and gravel deposits of the Adirondack region of New York state are rich in gold and precious metals; one which, in spite of repeated demonstrations to the contrary, is still able to inspire hopeful investors with dreams of fortunes to be won.

Around the border of the Adirondack region of New York state, in Saratoga, Warren, Essex, Herkimer, Lewis, and Fulton counties, a vast sand plain occurs. About 1880, William T. Bullis, of Glens Falls, New York, became convinced that he had discovered gold in the sands of that region, and devoted the rest of his life to fruitless schemes for recovering, by barrel amalgamation, gold which could not be detected by fire assays.

About the same time Mr. C. P. Bellows, a dental practitioner of Gloverville, became interested in the sand deposits, and has since remained the chief factor in maintaining a belief in their value. The discovery of the rich gold deposits of the Klondike region gave a tremendous impetus to faith in the richness of these sands, and during 1898 over 4000 claims were filed with the proper state authorities.

Much the most ambitious attempt to recover gold from the sand was that by J. E. Sutphen, who, about the same time, devised a secret process and built a mill for the purpose on the Sacandaga river, near Hadley, Saratoga county. After treatment with a mysterious chemical mixture, the sand was ground in amalgamating barrels and was claimed to yield $7.50 per ton. This mill was described in some detail by Mr. J. Nelson Nevius in the report of the New York State Museum for 1898. Mr. Nevius' samples of the sand being treated by the mill gave no more than a trace of gold. Careful tests made on the Adirondack material by such competent firms as Ledoux & Co. showed conclusively that the amounts of gold present do not exceed the traces which can be found in many rocks, nor is there any possibility of the presence of mysterious substances which prevent the recovery of the gold in an ordinary fire assay. In September 1910 Mr. D. H. Newland, assistant state geologist of New York, published the following statement:

"Without indulging in criticism of the good faith of those who have been at work on the Adirondack sands, we are unable to find in the notices of the press or in any literature which has been circulated for the purpose of informing the public as to their claims, any satisfactory explanation of the processes employed for recovery of the gold which would account for the wide variance between their reported results and those obtained by the usual assay methods. We have been informed recently on creditable authority that in the so-called 'Sutphen' process, which was extensively advertised about 10 years ago, the methods consisted briefly of pulverizing the sand and amalgamating it after treatment with a hot sodium carbonate solution. It was stated that the gold had a silicious coating which necessitated fine grinding and chemical treatment before amalgamation was effective. Even if that were true, there is no reason why the gold should not be set free by fire assay. On the other hand, the claim that the gold exists in volatile state, something entirely new to chemical science, seems to be met and controverted by the recent assays. The economic record of past enterprise in this field is certainly not reassuring to those intent on new ventures. Though it is impossible to give an accurate estimate of the outlay of capital represented by previous experiments, the total must amount to several hundred thousand dollars. An idea of the wide interest which the early enterprises aroused may be gained from the official records which show that over 4000 claims to gold and silver discoveries, mainly within the Adirondacks, were filed in the year 1898. We know of no instance where the public has received any financial return for its investment."

It might be supposed that the belief in the value of the Adirondack sands would have been given its quietus by these disclosures, but such was not the case. The Waverly Reduction Company, which held some 2000 acres in Franklin county, and of which A. E. Copp, of Boston, was president, continued its activities in attempting to recover the 'immature' gold of the sand. E. C. Jordan and G. R. Thurber were authors of schemes for this purpose, and shares in the Company were being marketed by the Union Securities Company of Hartford, Connecticut, until the publicity given it by the New York *Sun* early in 1912 blighted its career. A mill built at Lowville, New York, by N. S. Keith, of Philadelphia, which was claimed to recover an average of over $2 per ton of sand, was subjected to a test run by two competent mining engineers, Messrs. John T. Roberts, Jr., and W. G. Barney, and yielded less than 5 cents per ton. In spite of all these fiascos, the faith of Mr. Bellows continues unwavering, and he has succeeded in selling tracts of land to credulous investors in many of the eastern states, but especially to residents of Philadelphia. Messrs. E. H. Godshalk and Edward W. Patton, of that city, have each recently built mills on the tracts which they have purchased, and George P. Brock and C. J. Rothermel have purchased a 150-acre tract. F. S. Lewis, formerly president of the Lake Superior Corporation, an enterprise likely to be long remembered in Philadelphia, has likewise been active in these ventures, and the claim that recent results show that the sands contain $5 per ton in gold and platinum rests on the authority of John Ogden, who was formerly as assayer of Denver. So many Philadelphia people have become involved in these Adirondack schemes, in one way or another, that to mention them all by name would be tedious.

So long as these people are risking only their own money (and most of them are making no appeal to the public) in ventures which offer no chance for success, it might seem that it is no concern of the mining profession. Such is not the case, however. Every mining fiasco, based on groundless hope and engineered by men without mining knowledge and experience, reflects on legitimate mining, from which the general public is unable to distinguish it. Each year it becomes more difficult to find men willing to risk money in intelligent and well directed prospecting, which must precede development work. The East is the great centre for capital; over three-quarters of the income tax receipts for the entire United States is from New York and Pennsylvania. Mining misadventures such as these, occurring close at home, inevitably act as a deterrent to the furnishing of capital for prospecting and developing mines in the western states, where the deposits actually exist. It is to the disadvantage of the mining profession as a whole that belief persists in such baseless schemes, and engineers owe it to themselves to endeavor in every way possible to publish the truth.

Friendliness v. Friction at the Bunker Hill & Sullivan

By JOHN A. GOODELL

*The one element that modern business cannot reduce to mathematical formulas and stereotyped rules of efficiency, is the human. It defies mathematical regulation, is always developing an unknown quantity to be reckoned with, and it refuses to 'come out even,' in accordance with mechanical standards which work so smoothly on the inanimate equipment of a big business plant. This was demonstrated back in 1903 by the dark and stormy times of industrial war in the Coeur d'Alenes. After the smoke of that conflict cleared, the officers of the Bunker Hill & Sullivan Mining & Concentrating Co. settled down to some hard thinking, and, as we all know, a little thinking goes farther than a great deal of fighting. In this case the thinking resulted in full recognition of the human element. The men were encouraged to organize a club of their own in the nearest town, Kellogg, Idaho. Meantime, R. D. Handy had been away at the Company's smelter and became acquainted with the work of the Industrial Y. M. C. A. He came back with a story of the friendly reception he had met from the secretary, and of the good fellowship that had

SOCIAL ROOMS, A CLASS IN SPANISH, THE BUILDING, BOYS' CLASS, AND READING ROOM, KELLOGG INDUSTRIAL Y. M. C. A.

*Previous articles in this series are: 'Big Returns on an Investment,' by Fred H. Rindge, Jr., November 7; 'Welfare Work Among Mine Workers,' by L. F. S. Holland, November 14; and Safety Work at Calumet & Hecla, 'Looking Forward,' December 19.

GENERAL VIEW OF KELLOGG, IDAHO.

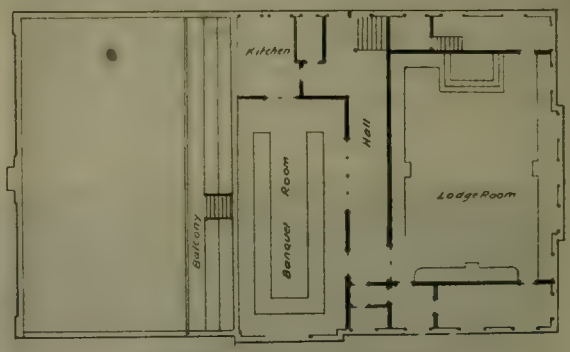
resulted. It struck Stanly Easton, the capable and cordial manager at the mines, that perhaps here was the very thing he was looking for, and he promptly began an investigation of the Industrial Y. M. C. A. The result was that an organizing secretary visited him and an agreement was reached whereby the Company began the erection of a building costing $35,000 to be the home of the Kellogg Industrial Y. M. C. A. The building is now finished. Its arrangement and uses are indicated by the floor plans illustrated. The activities it shelters mean an almost unbelievable amount of good, not to the men of the Company alone, but to the entire community. It houses the labor organization. In the basement are double bowling alleys, in constant use, the women having possession two afternoons a week. There is a billiard room of five tables. In the basement also, are a large locker room and the swimming pool. On the main floor are reading rooms, class rooms, a public library, and offices. A well equipped gymnasium occupies about half the floor space here. The accompanying illustrations give glimpses of the work.

The financing of all these activities is an important consideration. It is on the basis of mutuality. The Company contributes heat, light, and $1500 yearly in cash, and also donates the rent for the second story, which is occupied by the labor organization. This amounts to something over $375, and is set aside by the secretary of the association for the upkeep of the library and the purchase of new books. What the men pay is in the form of memberships, as in any club.

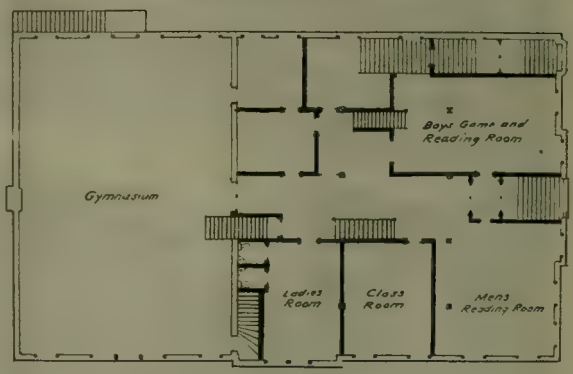
Statistics for the year 1913 show that books taken from the library in eight months (there are about 7000 volumes to choose from) amounted to 4118; attendance at educational classes was 1598; letters written, 10,460; attendance at gymnasium classes, 5044; baths taken, 23,347; number of games used, 16,812. Of course, an organization of men without baseball is not possible in the United States, so the Kellogg Industrial Y. M. C. A. has the 'Twilight Baseball League,' consisting of eight teams, which played last year to an attendance of 10,125.

Social events are of frequent occurrence. Among them bowling tournaments are popular, usually closing with a banquet and the awarding of prizes. Then there is the annual 'Open House' of the association, at which last year, as an interested guest of his employees was F. W. Bradley, of San Francisco.

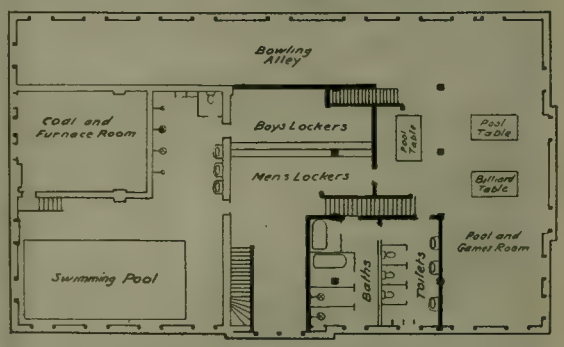
The active man in the enterprise is J. E. Sturdevant, secretary. His duties are manifold and beyond the possibility of exact specification. Generally speaking, they



UPPER FLOOR, Y. M. C. A. BUILDING.



MAIN FLOOR, Y. M. C. A. BUILDING.



BASEMENT, Y. M. C. A. BUILDING.

embrace the task of being a friend to every man in the community.

It cannot be emphasized too strongly that this centre is not for the men of the association alone, but for every man, woman, and child in the community. After four years' experience with the Industrial Y. M. C. A., Mr. Easton, who has been a thoughtful and active friend of the work from the first, says: "The institution has made good in every sense of the word, and we feel that our support of it has been fully justified by the direct and indirect results secured."

Gold Mining and Milling in the Southeastern States

By W. R. DODGE

In the present-day search for new fields in gold mining, more attention could well be directed to the southern Appalachian region in the states of North Carolina, South Carolina, Georgia, and Alabama.

This is the oldest gold mining territory in the United States, gold having been discovered in the early part of 1800. Considerable activity was shown here in the early thirties and forties when this region supported a mining population of 15,000 to 20,000 with a production of $1,000,000 per annum. There were then United States mints at Dahlonega, Georgia, and New Orleans, Louisiana. Later a United States assay office was established at Charlotte, North Carolina. The California gold excitement in 1849 caused the emigration of the major portion of these miners, who introduced the rocker, long-tom, riffled sluices, much hydraulic equipment, and probably the stamp-mill into that state. These old southern miners gave the first impulse to gold mining in California. The Civil War caused almost complete cessation of mining in the South; the production since then has been but a fraction of that previous to the war.

Gold mining in the South has never enjoyed the systematic development or persistent effort which has characterized other parts of the United States, the reason for this being that when gold was first discovered the country was already a closely settled farming community and the planters looked askance at mining and were much adverse to having their plantations over-run by prospectors or torn up by the surface mining of that time. Those, then, who did engage in mining devoted a part of their efforts to farming and a part to mining on their own tracts. This in part is also the condition at the present time.

The Gold-Bearing Areas

The gold-bearing rocks are largely crystalline schists which extend over a wide area from Montgomery, Alabama, to Washington, D. C. This includes the whole western half of North Carolina; the northwestern half of South Carolina; the northern half of Georgia, and a triangular district in eastern Alabama containing the counties Cleburne, Randolph, Talladega, Clay, Tallapoosa, Chambers, Coosa, Elmore, and Chilton, some 3500 square miles. This area has been divided into belts, the most important ones being as follows: the Carolina belt; the Georgia belt; the Alabama belt. The Carolina belt is the most extensive. It extends from the south boundary line of Virginia in a southwest direction across the central part of North Carolina into the northern part of South Carolina, where it sinks below the Coastal Plain, making its reappearance in Abbeville county, South Carolina, and in Wilkes, McDuffie, and adjacent counties in Georgia near Augusta. Its width is from 8 to 50 miles. The Georgia belt begins in Rabun and Habersham counties, in the northeastern part of the state, and extends southwest through Dahlonega to the Alabama line near Tallapoosa, Georgia. Its width is from 4 to 30 miles. The Alabama belt may be considered an extension of the Georgia belt.

Country Rocks

In the Carolina belt, these consist mainly of metamorphosed slates and schists, including devitrified volcanics (rhyolite, quartz-porphyry, etc.). Its western boundary is made up of igneous rocks (granite, diorite, etc.). Among the slates forming the eastern boundary are the important Monroe slates. These are probably sedimentary and are highly silicified. They occur in Monroe, Stanly, and Montgomery counties. The general strike of this formation is N.20 to 55°E. and the predominating dip 55 to 85° northwest. The Georgia and Alabama belts for the most part consist of micaceous, hornblende gneisses, and schists, often garnetiferous. The prevailing strike is N.20 to 30°E. and dip 30 to 60° southeast.

Gold Ores

In the Carolina belt, the gold ores occur as quartz fissures and disseminations of fine gold and pyrite accompanied with irregular quartz stringers and lens-shaped fillings, usually in the cleavage planes of the schists and slates. The quartz fissures are more apparent in the eruptive rocks, and scarcely discernible in the schists and slates. Silver, lead, zinc, and copper also occur in this belt. In the Georgia and Alabama belts, the gold ores exist in numerous small veins, stringers, and lenses of quartz, aggregated in zones or belts which taken together form the orebody. This is sometimes hundreds of feet in width. Gangue minerals are pyrite, rarely chalcopyrite, garnet, monazite, tourmaline, and bismuth. Weathering agencies have decomposed and softened these rocks from the surface to water-level, varying from 50 to 150 ft. in depth. Such orebodies are called 'saprolites.' The quartz is left unaltered, but is broken. The sulphides are oxidized and the gold changed to the free state. The mining of these large, soft orebodies is rendered simple and profitable.

Mining

This has consisted of both placer and deep vein mining. Nearly all of the early work was confined to placer mining. The placers consist of three kinds:

1. Beds of streams and ancient river channels: the latter being often filled in and obstructed from view. In some cases these penetrate into the hillsides. The 'pay' is shallow (1 to 2 ft. thick) and consists of rounded pebbles and nuggets. Large nuggets have been found in Mecklenburg and Montgomery counties, North

Carolina: White county, Georgia; and the Arbacoochee district, Alabama. The largest (28 lb.) was found at the Reed mine, North Carolina.

2. Placers consisting of vein quartz eroded from hill-sides and collected in concentrated form in synclinal basins and at the mouths of gullies. The nuggets in these deposits are in the form of wire, sheets, and flake gold, and are much smaller than those of the river beds. These placers are small compared to those of California and have only been operated by the crudest methods. No records have been kept as to the values per cubic yard. The average values are given as 15c. to $1 per yard. Extensive hydraulic plants with giants and gravel elevators have been operated in the neighborhood of Dahlonega, Georgia, and in the Arbacoochee district of Alabama. There is little placer work now being done, although it is said there is virgin territory in western North Carolina and in the Arbacoochee district. A company with headquarters at Birmingham, Alabama, is operating a dredge in the Arbacoochee district, near Heflin, Alabama. Details are lacking. Dredges have also operated near Dahlonega, Georgia.

The Saprolite Ores

3. Saprolites. This term has been given to the decayed outcroppings of veins and means literally, rotten rock. They form the most interesting deposits from the point of economic geology. From them the greater part of the gold has been won in the past, and on account of their wide extent will in the future be mined.

These saprolites contain narrow quartz veins from 1 in. to 2½ ft. thick and innumerable lenticular quartz stringers which are for the most part gold bearing. Gangue minerals are garnet, black sand, and unaltered pyrite, which is also gold bearing. Where these veins and stringers come closely together they may be worked as one orebody. The value of such lodes ranges from $3 to $6 per ton and their width is as much as 50 to 100 ft.—as at the Rudisil mine, Mecklenburg county, North Carolina. Such deposits are treated as lodes and are mined by labor and milled in stamp-mills. Where the small veins and stringers are more widely separated, lower values are the rule and the ore is mined as in placers. When these saprolite deposits are upon a hillside or are cut by gulches they are favorable for hydraulic mining.

Dahlonega, Georgia, has been the centre of greatest activity in working these deposits and here was originated the Dahlonega method of mining and milling. This consists of hydraulic mining with 'giants,' the soft decomposed material, which is carried by flume (containing riffles) to the stamp-mill. Here the pulp is received in a large bin behind the stamps. This bin acts as a crude classifier. It has a discharge opening at one end partly closed by slats spaced one-half inch. Here the larger pieces of quartz are retained while the mud and finer quartz escape to waste. What quartz remains in the bin is milled through the stamps, the pulp passing over amalgamating plates. The plant is simple as to first cost, and the operating expenses very low, but the waste of fine gold is excessive from both the bin and the stamp-mill. Costs are given as 25c. per ton and the saving as 35%. Such plants have been in operation also at Auraria, Georgia, and in Stanly county, North Carolina.

Other methods of working those saprolites are with log-washers. There are two types of these machines, the high-speed and the low-speed. The former type consists of two units of double log-washers acting in tandem. The logs are usually 12 to 18 ft. long and mounted in steel troughs with straight sides and a rounded bottom. Provision is made for a wooden cover. At the discharge end of each machine is a revolving screen or trommel. That following the first machine is coarser than the second. The size of the screen openings is optional with the operator. The logs revolve at high speed, No. 1 at 100 to 150 r.p.m., and the second at 200 r.p.m. The soft ores are fed, together with water, to machine No. 1, and thorough disintegration is allowed to take place. The coarse trommel at the discharge end removes rocks and roots, which are delivered to a conveyor and carried to waste. The pulp passing to the second washer receives more water. The pulp is discharged from this machine, and after passing the second screen (about 4 to 6 mesh) is passed over riffles containing mercury. The oversize of the second screen likewise goes to waste. Some coarse gold remains in the washer troughs and is periodically removed.

Such a plant treats 10 tons per hour and requires 75 gal. per minute and 25 hp. to operate. No attempt is made here to mill the coarser quartz.

Another combination of equipment is the slow-speed log-washer, a single unit being used. The logs are longer, 20 ft., and the speed is 15 r.p.m. The washers have a square bottom which fills up with coarse quartz. The washer disintegrates and removes the clay, delivering the washed quartz to a Huntington or Chilean mill.

Very little work is being done with these saprolite deposits at the present time, although they form the most valuable in the South. Nearly all the orebodies can be mined by a steam-shovel.

Results of Ore Test

An ore test that I made may be interesting at this point. A sample of oxidized saprolite ore was first treated in its natural state by cyaniding (all slimed to 100 mesh, as leaching was not practicable). Another portion was washed to eliminate the clay and to recover the quartz in a concentrated condition. This washed product was treated by cyanide, the same as the original ore.

	Per ton.
Original ore value	$2.20
Extracted by cyanide (86.4%)	1.90
Washed ore from original (ratio 5:1)	8.00
Extracted by cyanide, washed ore (92.5%)	7.40
$7.40/5 equivalent to extraction on original	1.48
Difference $1.90—$1.48	0.42

Favor cyaniding crude ore direct.

Cost of treatment (assumed): (1) Based on mining by labor, 100 tons crude ore. This treated by all-slimming cyanide process, agitation, filtration, zinc-dust precipitation, etc. (2) Steam-shovel mining of 500 tons crude ore. This reduced by washing to 100 tons and treated in the same mill as above.

		Per ton of crude ore.
(1) Extracted by cyanide		$1.90
Mining and delivery to mill	$0.35	
Milling and cyanide	1.50	
	1.85	
Profit		$0.05
(2) Extracted by cyanide, washed ore	$7.40 or	$1.48
Mining, washing, and delivery to mill	$0.65	
Milling and cyanide	1.50	
	2.15 or	0.43
Profit per ton washed ore	$5.25 or	$1.05
Difference in favor of washed ore		$1.00

Deep Vein Mining and Milling

The South has no bonanza gold mines as this term is understood in the West. The veins, for the most part, are small, 2 to 6 ft. being an average width.

There have been some exceptions, as the Haile mine, Lancaster county, South Carolina; large lens-shaped orebodies 80 ft. thick. Capps mine, Mecklenburg county, North Carolina; vein 20 ft. thick, etc.

The veins usually follow the general strike of the country rock in which they occur, except in those cases where the veins are split and turned aside by 'horses.'

The general strike of these veins is northeast. It is noteworthy that enrichments occur along the intersections of cross veins, having a northwest strike, or in some cases east and west. Exceptional values are: Stephen Wilson mine, Mecklenburg county, North Carolina, $345 per ton, vein 2 to 3 ft. wide; St. Catherine mine, Mecklenburg county, North Carolina, $27 to $180 per ton, vein 2 to 6 ft. wide.

The majority of these mines are worked crudely at the surface as pits, open cuts, and shallow shafts. As long as the ores were free milling the gold was recovered in rockers, sluices, or small stamp-mills. When water-level, harder formation, or the sulphides were encountered, the workings were abandoned and a new pit sunk. Thousands of these shallow workings exist along these gold belts.

Few of the mines of the South are equipped with modern milling plants, the general practice being stamp-milling followed by amalgamation and concentration.

A few mines in the last decade adopted the Thies chlorination process for treatment of concentrates. This process consisted in roasting the concentrates in hand-rabbled reverberatory furnaces and, after cooling, chlorinating in one-ton barrels by the use of bleaching powder and sulphuric acid. The gold-bearing solution was filtered through a sand filter and precipitation effected by means of ferrous sulphate. The cost of treating 12 to 15 tons per day was about $3 per ton.

Although amalgamation and concentration have outlived all other processes, the saving has been low. The average by amalgamation is about 35%, rarely 50%. Concentration effects 15 to 35% more, the loss being in fine and rusty gold. The usual hard quartz ores retain the gold in a very finely divided state. After passing a 30-mesh battery screen, much of this gold is almost microscopically small and, being suspended in the pulp, is not amenable to saving by these mechanical processes.

Early attempts with the cyanide process were not encouraging. In some cases the leaching process was tried, but as no separation of slime from the sand was made, a very poor extraction resulted. In other cases the ores were not crushed fine enough to liberate the values. Thus, for one reason or another, the various attempts did not succeed.

The Iola mine, Montgomery county, North Carolina, has the distinction of being probably the first to erect a successful modern cyanide plant, treating both the soft oxidized ores and the hard compact ores from below water-level. This mine is in the Carolina slate belt. The ores are very hard and tough slate with quartz. The vein is about 2 to 3 ft. wide, and the sorted ores run in the neighborhood of $13 per ton. The production is about 65 tons per day, and this is reduced by sorting to 50 tons. The cyanide mill has every modern accessory, consisting of five 1750-lb. stamps, 7-in. drop, 107 drops per minute. Screen aperture is about $\frac{1}{3}$ in. and stamp-duty is 10.5 tons.

The resulting pulp is all-slimed in a 4 by 20-ft. tube-mill with a Dorr duplex classifier in closed circuit. The slime is thickened in a Dorr thickener and then agitated in three Parrall agitators in series. After agitation, filtration takes place in a Kelly filter. The slime cakes are passed through a disintegrator and sluiced to the dump. The solutions are precipitated on zinc shavings. The extraction is in the neighborhood of 95%, and the cost of milling and cyaniding is about $1.64 per ton. A special feature to be noted is the non-colloidal nature of the slime. This ore when ground to 200 mesh still retains its crystalline properties, and settles rapidly, thereby requiring a pressure filter rather than a vacuum.

The Uwarra Mine and Mill

The Uwarra gold mine, Candor, Montgomery county, North Carolina, adjoins the Iola property on the north. Development of the mine was carried on for about a year previous to the erection of the mill. The underground workings aggregate a mile, and several thousand tons of ore is blocked out. The ore is similar to that of the Iola, and 50 tons is passed through the mill, which is thoroughly modern. The ore is hoisted from the mine in cars and trammed over a trestle to the crusher ore-bin. From this it is fed to a Blake crusher and crushed to pass a 1¾-in. ring. The crushed product is delivered on a belt-conveyor (22° incline) which carries it to the steel cylindrical mill bin. From

this the ore is automatically fed to crushing rolls and crushed to pass ¼-in. mesh. This product is delivered to a classifier with mill solution. The slime is separated and the coarse ground in a 5 by 20-ft. tube-mill. The slime was thickened and then agitated in mechanical agitators, afterward being elevated to storage and filtered in a pressure filter.* The solution is precipitated on zinc shavings.

The Hog Mountain gold mine is situated near Alexander City, Alabama. This property has had a long, successful record. The ores here are quartz. The surface ores were dry crushed by rolls to ⅛-in. mesh, then trammed to 125-ton vats and leached with cyanide solution. Recent improvements for treating the hard refractory sulphide ores consist of crushing dry with rolls, tube-milling with cyanide solution, and passing the tube-mill discharge, without classification, over blanket tables to the leaching tanks. A 75% extraction was made on a $5 ore, distributed as follows: Extraction in tube-mill, 8%; concentrates, 42%; leached in tanks, 25%; total 75 per cent.

The concentrates were re-run over blankets, and, as shipped, assayed over 100 oz. gold and 15 oz. silver. The concentrates also contain several per cent of bismuth. This mill is operated by hydro-electric power, and costs are very low.

In conclusion, it may be said the southern gold ores are no more difficult to treat than the ores of other sections of the United States, nearly all the surface ores being amenable to cyanide treatment.

Further, the South has in its favor an excellent climate, without the drawbacks of the desert or the frozen mountainous districts of the West.

There is generally an abundance of good water, and water-power is available, or can be made so, in many of the districts.

Fuel, lumber, and all mining supplies can be laid down at the property at much less cost than in the West. Although common labor is cheap, the better labor and skilled labor commands about the same prices as in the West.

With all these favorable conditions, the South should take first rank for producing an ounce of gold at less cost than any other section of North America.

WASTE-ROCK GOLD CONTENT was the subject of an impromptu discussion at a meeting of the Chemical, Metallurgical and Mining Society of South Africa on October 17, 1914. The arguments were interesting, but the members decided that it was informal, and the discussion, therefore, will not be published.

GOLD OUTPUT of the East Rand Proprietary mines, Transvaal, in November, totaled 51,633 oz. from 165,000 tons of ore, crushed by 820 stamps and 25 tube-mills. The profit was $336,000.

---

*Use of the agitators has been discontinued and other changes made in the flow-sheet, as shown by Andrew Walz, *Mining and Scientific Press*, December 12, 1914.

Mineral Production of the Dutch East Indies

The principal islands of the group are Banka, Billiton, Borneo, Celebes, Java, and Sumatra. The production of the government tin mines at Banka during last year was 34,481,168 lb., and of the Billiton (private mines) 10,064,816 lb. Some 4,938,800 lb. of Billiton tin was sold at Batavia during last year. Government tin is shipped to the Amsterdam, Holland, market for sale, and during 1913, 32,127,525 lb. was exported on government account. There were no shipments of tin to the United States during 1913.

The Ombilien coal mines (government) in southwest Sumatra increased their output from 408,204 tons in 1912 to 411,083 tons in 1913. This coal was formerly exported to the Straits Settlements and China, but during last year the output was used by the local government. The price of Ombilien coal during the past year was about $6 per ton.

The Puloe Laut coal mines (southeast Borneo) have been purchased by the Netherlands India government during the past year for, it is stated, about $1,280,000.

The Samarinda (East Borneo) coal mines also belong to the government, and produce a fair quantity of inferior coal, which is used entirely for local purposes.

The general output of the few gold mines in this colony during last year was considerably below that for the previous year, and the only two mines giving any results were the Redjang Lebong, Sumatra, producing during 1913 $1,050,000 worth of gold, and Simau, Sumatra (near Redjang Lebong), producing $880,000, and the Ketahoen nearby. While the production of the Redjang Lebong is decreasing each year, that of Simau shows a slight increase. There are two gold mines in the Celebes which, during 1913, produced some gold, namely, the Paleleh and the Totok, with outputs valued at $365,000 and $330,000 respectively.

The oil industry in Netherlands India (Borneo and Sumatra) continues successful, and the output is increasing each year. The yield for 1913 is reported as 1,503,660 tons.—*Daily Consular Report.*

A COMPLETE ANALYSIS of coal gas made in Pittsburgh is as follows:

Constituent.	Formula.	Per cent.

Draining Kerr Lake at Cobalt, Ontario

By BEN HUGHES

*Operations in the draining of Kerr lake of water and mud so that it could be prospected from the surface ceased for the year in the second week in November. It was hoped at the beginning of the year that the bed of the lake would be cleared before the frost stiffened the mud, but the boulder clay presented problems that had not been fully considered. Much preliminary work had to be completed before it was possible to start the actual dewatering of the lake, but actual pumping commenced August 28, 1913. An amendment had been inserted in the mining act of Ontario which made it possible for companies to undertake the draining of the lake in order to reach ore. The owners of the Drummond mines made objection and carried their case to the courts. Finally the matter was settled by the Kerr Lake Mining company and the Crown Reserve Mining company buying what is known as the Drummond Fraction, consisting of seven acres under the lake and some littoral, for $150,000.

No further incentive to drain the lake was needed than that up to the end of the year before the work actually commenced, the Crown Reserve Mining company had won 17,003,821 oz. of silver, all from under the 42 acres which the lake originally covered. A considerable portion of the very heavy production of the Kerr Lake Mining company also was from below the water line, and the Drummond Fraction presented ground well worth prospecting. All these mines had raised on their veins under the lake as far as they could with safety.

Drainage operations have been carried out jointly by the Kerr Lake and the Crown Reserve mining companies. From the nature of the lake the Kerr Lake has been the first to obtain definite results. This Company has opened its 10 and 17 vein systems on the surface as well as numerous stringers, and the resulting discoveries have undoubtedly added to the life and value of the mine. The whole of the Kerr Lake area under the lake will probably be cleared of detritus next year. The rewards will come more slowly to the Crown Reserve, as the acreage to be cleared lies right in the bed of the lake. Eight acres have yet to be cleared of boulder clay before

*I am greatly indebted for most of the details contained in this article to H. G. Stewart, superintendent for the Crown Reserve Mining Company.

REMOVING MUD FROM BOTTOM OF THE LAKE BED.

surface prospecting can be efficiently undertaken. The dewatering of the lake proved to be a minor problem compared with that of taking out the mud, and that again was a much simpler problem than the pumping of the clay. During the winter, while the pumps are inactive, a certain amount of water naturally finds its way back into the lake, but last spring it only required eight days to pump it dry, so that this does not play any considerable part in the operations.

Results at Kerr lake are being carefully watched in other portions of the district, where preparations have been made or are contemplated for the draining of lakes and the recovery of known or probable ore underneath them.

The area of Kerr lake amounted originally to 42 acres, of which the Crown Reserve Mining Co. owned 23, Kerr Lake Mining Co. 12, and Drummond Mines 7. A ditch was dug by the Crown Reserve Mining Co. some six years ago from the west end of the lake and leading to Glen lake. By this means the lake level was reduced by eight feet, clearing sufficient area of the Crown Reserve to erect necessary buildings. For the recent work a scow was erected, the dimensions of which were 40 by 20 ft. and the depth 4 ft. It has approximately 70 tons displacement. On this scow was erected four single-stage centrifugal pumps which were arranged in two units, each unit consisting of a compound pumping outfit of two pumps direct-connected by a flexible coupling to a 250-hp. motor. The suctions were 12 in. and discharges 10 in. The runners are of the enclosed type and capable of delivering boulders up to approximately 4 in. diameter. Each of these units was capable of delivering 3000 gal. per minute on a maximum head of 185 ft. with an efficiency of approximately 65%. When the pumping operations were begun, the four pumps worked in parallel, each discharging into a 14-in. pipe and thence to the 20-in. main line. When the level of the lake had been reduced by approximately 15 ft., a change from operating the pumps in parallel to a series of two units, was made. By this means, two units each of a two-stage tandem pump were obtained. While the volume of water pumped decreased, still the efficiency of the outfit was increased to approximately 75%. For priming purposes, a small air-driven plunger pump was used on the scow. During the early period of the operations, the water for this purpose was secured from the Kerr lake, but as the work proceeded and the water became muddy, it was necessary to secure it from the fresh-water plant at Giroux lake. Two of the flexible joints were used in order to allow for any swings that might take place. One was placed on the scow and another upon a concrete pier on the shore. It is the intention to place another half way between these points, set on wheels, which in turn will be on a track so as to allow for a maximum horizontal swing which might take place owing to the mud-slides or other accidents. The water from this plant was handled through a 20-in. spiral riveted pipe, from which it was conveyed to Giroux lake, where it was discharged. Expansion joints were also placed in the line at certain points which each would allow for 16-in. plug. A 12-in. bypass was also put in which would allow for draining the line when necessary.

To date, a total amount of 635,000,000 gallons of mud and water has been pumped, and the lake has been lowered an average of 65 ft. This is an approximate figure, as owing to the depression at the lake bottom, it is a difficult matter to get the correct depth.

At the time that pumping was begun, a fresh-water plant at Giroux lake, consisting of two 500-gal. centrifugal pumps, direct-connected to 45-hp. motors, was erected to supply fresh water to the various mines affected by the drainage operations.

During the past summer, a pump of 5000-gal. capacity was installed to furnish necessary water for hydraulicking purposes. This has consisted largely of cutting channels in the mud bed to a certain point, and then retreating back to the scow, breaking down the sides on the return. This scheme has worked satisfactorily, and it is hoped that after another summer's operation the mud will be almost removed from the bottom of the lake.

The Origin of the Dolomites

By FRANCIS M. VAN TUYL

*A careful study of the dolomites of the upper Mississippi Valley was undertaken for the Iowa Geological Survey during the field season of 1912. More recently a grant from the Esther Herrman Research Fund of the New York Academy of Science has made possible much more extensive studies of the dolomitic limestones of the Eastern and Central states. The present preliminary paper is intended merely to set forth some of the more important results of these studies.

Previous theories of the origin of dolomite are briefly considered, after which the problem is attacked from three standpoints, namely: the experimental evidence; the field evidence; and the petrographic evidence. The conclusion is reached that the great majority of the dolomites, ranging in age from the Cambrian to the present, have resulted from the replacement of limestones before they emerged from the sea. The replacement need not be accompanied by shrinkage, as formerly supposed, but may proceed according to the law of equal volumes, as enunciated by Lindgren. Furthermore, certain cases of apparent interstratification of limestone and dolomite cited as evidence in favor of the primary theory are rather pseudo-interstratifications, which have resulted from selective dolomitization. Examples of limestones mottled with dolomite are interpreted as representing an incipient stage of the process of alteration. Organic factors have exerted a selective influence in some cases of mottling, but in others the phenomenon is purely inorganic.

*Abstract of a paper read before the Geological Society of America, Philadelphia, December 29-31.

Rhythmic Precipitation of Ferrous Ferri-Cyanide and Ferrous Hydroxide in Jelly

By H. J. M. CREIGHTON

*When a drop of silver nitrate solution is placed on a thin layer of gelatin containing potassium dichromate, silver chromate precipitates out in circles which are concentric to the drop of silver nitrate. This precipitation of silver chromate has been investigated during the past few years by Liesegang and others.[1] Analogous phenomena have been observed by Liesegang[2] with mercurous chromate, lead chromate, and Prussian blue, and by Morse and Pierce[3] with lead sulphate, silver carbonate, phosphate, bromide and thiocyanate, cobalt hydroxide, barium chromate, and mercurous bromide. This phenomenon of rhythmical precipitation is explained by Ostwald's theory of supersaturation.[4] I have recently observed phenomena similar to the foregoing with Turnbull's blue and ferrous hydroxide.

The horizontal part of a glass tube 70 cm. long and 2 cm. in diameter the ends of which were bent up at right angles, was filled with a 10% solution of agar-agar containing small quantities of potassium ferri-cyanide and sodium chloride. After the jelly had solidified, the vertical arms of the tube were filled with a dilute solution of sodium chloride, and an iron electrode, made from a clean wire nail, was placed in the liquid in each arm. An electric current having a potential gradient of 0.00679 volt per cm. was then passed through the jelly.

Within a short time after the current was started, the end of the jelly near the anode became blue, and for four days the blue color continued to advance through the jelly. During the following 24 hours there was no perceptible advance of the color, but at the end of this time a very thin dark blue layer or disc was observed to have formed in the jelly at right angles to the axis of the tube. This blue disc gradually increased in thickness during the next few hours until it attained a width of 1 mm. This disc, which was more intense in color than the blue jelly behind it, was separated from the latter by 3 mm. of practically colorless jelly. At the end of another 24 hours a second disc had formed which was separated from the first by 4 mm. of colorless jelly. In this experiment a new disc appeared every 24 hours, the discs forming in the direction of the flow of the electric current.

An experiment similar to the foregoing was carried out, except that the jelly contained small quantities of sodium chloride and phenolphthalein. The ferrous ions diffused into the jelly under the influence of an electric current having a potential gradient of 0.0093 volt per cm. The progress of the hydroxyl ions was followed by means of phenolphthalein. The ferrous and hydroxide ions, which were moving in opposite directions, met at the end of 115 days from the beginning of the experiment, and a dark green layer or disc of ferrous hydroxide was precipitated in the jelly at right angles to the axis of the tube. At the end of 24 hours, a second disc was observed to have formed. This was separated from the first by 3 mm. of jelly, colored pink by the phenolphthalein. Every day or two a new disc formed, each being separated from the preceding by several millimetres of pink jelly. The discs formed in the opposite direction to the flow of the electric current. The time at which each disc appeared, and the distance between each and the preceding one is shown in Table I. The ferrous hydroxide discs always commenced to form at the bottom of the tube and continued to grow toward the top, always sloping in the opposite direction to the flow of the electric current. Sometimes a new disc started to form before the preceding one was completed. In such cases the old disc ceased growing.

TABLE I

	Turnbull's blue discs.		Ferrous hydroxide discs.	
Number of disc.	Time of appearance of discs, days.	Distance between consecutive discs, mm.	Time of appearance of discs, days.	Distance between consecutive discs, mm.
1	0	...	0	..
2	1	4.0	1	3
3	2	4.0	2	5
4	3	5.0	3	3
5	4	4.0	4	5
6	5	3.5	5	4
7	..	...	6	4
8	..	...	9	6
9	..	...	11	4
10	..	...	14	6

The cause of the rhythmical precipitation of Turnbull's blue and ferrous hydroxide may doubtless be ascribed to supersaturation phenomena. As the Fe^{++} ions are carried into the jelly by the electric current, a metastable supersaturated solution with respect to Turnbull's blue first forms. Ultimately precipitation occurs and the $Fe(Cy_6)^{---}$ ions in the neighborhood are removed; the Fe^{++} ions then advance a few millimetres and form a new supersaturated solution, when the process is repeated. In the case of ferrous hydroxide, the OH^{-} ions form a supersaturated solution with the Fe^{++} ions. After precipitation has taken place, the OH^{-} ions must advance a few millimetres before a sufficient number of Fe^{++} ions are encountered to form a new supersaturated solution.

Prospecting Wet Placer Ground by Shaft Sinking

By DONALD STEEL

A rather general opinion seems to prevail among mining engineers that shaft sinking in loose wet ground is not a reliable method of prospecting. While this opinion may be in general justified, the work described below is thought to have given reasonably correct results.

The ground prospected was a loose creek wash averaging about 14 ft. deep with water-level at about 8 ft.

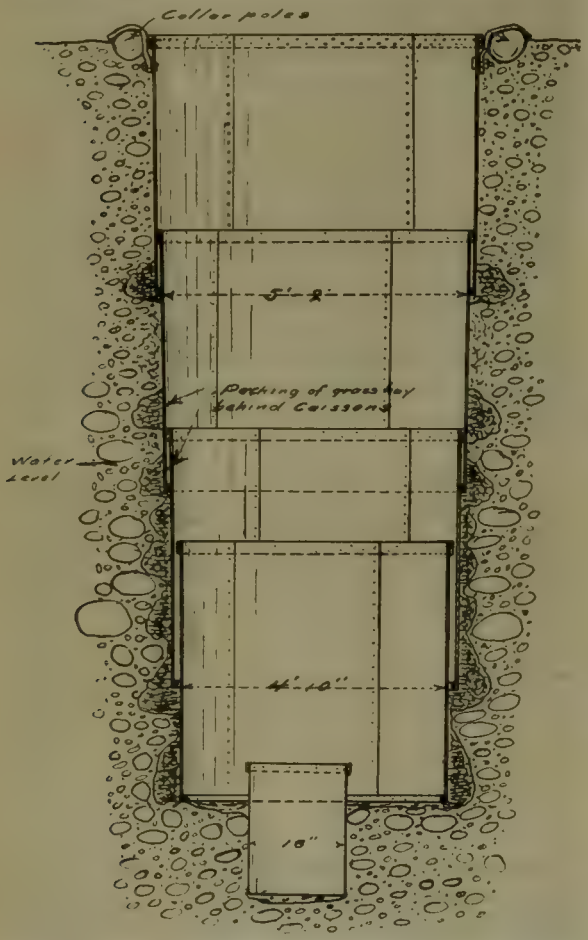

FIG. 1. SECTION THROUGH SHAFT SHOWING PACKING BEHIND CAISSONS AND METHOD OF SAMPLING BOTTOM OF SHAFT.

The greatest depth below water was in a hole 17.8 ft. deep with water-level at 6 ft. The crew required for this work was three miners and a panner, and the average speed of sinking was 4.4 ft. per 9-hr. day, including all lost time.

Equipment.—The main features of the equipment were:

1. A nest of seven caissons of ⅛-in. steel, 4 ft. long, and ranging from 5 ft. 2 in. to 4 ft. in diameter, slightly tapered to allow them to telescope readily. Each caisson had a band of ½ by 2-in. steel on the outside of the larger or top end, and a band ⅜ by 1¼ in. on the inside of the bottom end. These bands served as stiffeners and also to prevent the inner caisson from slipping entirely past the outer in telescoping. The method of using the caissons is illustrated in Fig. 1.

2. A windlass, bucket, and rope.

3. A sheet of heavy canvas covered with sheets of 16-gage iron for receiving the sample from the bucket.

4. A measuring box of ½-cu. yd. capacity.

5. A long-tom with accessories.

6. A 2½-in. pump with a 3½-in. suction and a 3-in. discharge, driven by a 4-hp. gasoline engine.

FIG. 2. LOADING A 4½-FT. CAISSON.

7. A 3½-in. pump with 3½-in. connections driven by a 6-hp. gasoline engine.

8. A small caisson, 18 in. diam. by 24 in. long, for taking samples in the bottom of the shaft.

9. A measuring box of 2-cu. ft. capacity.

10. A stump puller with cable, sheave, and hooks for pulling the caissons.

11. Two large canvases, cord, and sealing wax for sealing the shaft.

Sinking.—The ground above water was usually of comparatively low grade. In such cases a sample of 30-in. diameter was cut from the surface to water-level and kept apart until the shaft water should be sufficient for washing. As soon as this pit became so deep that there was danger of caving or it was difficult to shovel out, the bottom was covered with sacking and the pit was reamed out to the size of the first caisson. The caisson was then put in place and sinking was continued in the small pit. As soon as the first caisson was down, the next smaller was put in place and was lowered as sinking progressed. In some cases this system was varied by taking every fourth shovelful for the first sample, and in some instances water was brought

from the creek in a hose and the entire content of the shaft was washed as excavated.

At water-level an excavation was made around the outside of the bottom of the caisson and was filled with soft grass hay. The caisson was then driven down, leaving a packing of hay around the entire outer circumference. Care was taken below water-level to keep the bottom of the caisson close to the bottom of the shaft and to keep all space behind the caissons firmly packed with hay. In this way no considerable motion of ground was allowed to start, and the settling of the gravel on the packing served to shut out any flow of sand from above and a good deal of water. The bedrock was soft, so that high points could be removed, letting the caisson down around its entire circumference.

The efficiency of the packing was shown in several instances where shafts were sunk adjacent to others in which no packing had been used. As they were sunk at different times and by different engineers, no close comparison can be given. It is significant, however, that the required pump capacity and the amount of ground handled were noticeably less where the packing was used.

Sampling.—As it was impossible under the conditions to get an accurate measure of the space excavated, all figuring on samples from below water-level was done from measurements of the excavated material.

It was found by measuring excavations above water-level, and by settling the excavated material in a measuring box with water so as to fill the voids with fine material, that a close approximation could be made to the original volume. Where there was a considerable amount of soil present, there was generally a slight shrinkage in settling the excavated material. Where the gravel was solid, there was sometimes as much as 5% swell; but for the loose creek gravel the two measurements checked as closely as could be expected of two independent measurements.

At water-level, or as soon as considerable gold was found, the entire content of the shaft was saved and washed. In addition, whenever there was a marked change in value as indicated by panning, or whenever it was seen that sand was running under the caisson, a small sample from an 18-in. caisson was taken from the centre of the shaft as a check against the remainder of the shaft area. This sample was clearly not affected by run-in, and where it differed materially from the larger sample due allowance was made.

A new sample was started: (a) when there was a change in the formation or in the values as indicated by panning; (b) whenever a new caisson was put in, changing the diameter of the shaft; (c) whenever there was a shift of the crew.

FIG. 3. SHAFT EQUIPMENT: (1) LONG-TOM ENGINE; (2) LONG-TOM; (3) MEASURING BOX, ½-YD.; (4) SMALL MEASURING BOX; (5) CASING, 18-IN., FOR SAMPLING SHAFT; (7) CANVAS COVERED WITH SHEET IRON; (8) PUMPING ENGINE.

FIG. 4. WASHING PLANT: (1) SAMPLE OF IRON SHEETS; (2) MEASURING BOX; (3) LONG-TOM; (4) LONG-TOM ENGINE; (5) HOSE FROM PUMP.

Measuring Samples.—The plant used for handling and washing the samples is illustrated in Fig. 3 and Fig. 4. The material from the bucket was dumped on a 16-gage iron plate under which was a large canvas to prevent loss. From the plate it was shoveled into a measuring box of ½-cu. yd. capacity. This box was

made 2.4 ft. wide by 5 ft. long, so that each inch in depth represented one cubic foot. Water was poured into the box as the gravel was being shoveled in, and the larger rocks were buried in the finer matrial. When the box was full and well settled by puddling with a shovel and pounding on the sides of the box, it was marked on the log and washing was begun.

The long-tom driven by a 1¾-hp. gasoline engine, as shown in Fig. 4, proved a very efficient part of the equipment. One man with the occasional help of the pump tender had no trouble in washing the gravel as fast as delivered from the shaft and in cleaning up after each ½ yd. of sample. The riffles used were a combination of Hungarian riffle and cocoa matting with expanded metal.

Nature of material.	Vol. of hole, cu. ft.	Vol. excavated material, cu. ft.
1. Medium to coarse gravel	37.2	38.4
2. Medium gravel	22.4	23.0
3. Medium gravel	34.0	35.0
4. Fine gravel and sand	14.7	15.0
5. Medium gravel, surface to bedrock	46.0	45.0
6. Medium gravel, some sediment	19.6	19.0
7. Medium gravel	108.0	109.0

Figuring Values.—In figuring the results, the value per cubic yard of each sample was multiplied by the depth represented, and the sum of these products was divided by the sum of the depths, or the total depth of the shaft. A factor for swell was applied to this result, giving the average value for the hole.

In summing up the possible sources of any considerable error and the ways in which it was attempted to guard them, possible sources of error may be noted as: (1) error in measurement of volume; (2) salting of sample by fine material washed under the caisson; (3) inflow of barren sand and consequent lowering of average value; (4) loss by imperfect cleaning of bedrock; (5) loss in tailing; (6) possible wilful salting. Considering these, it may be noted that:

1. The close agreement of all measurements of loose materials with the measurements of their respective pits where these could be measured gives confidence.

2 and 3. The inflow of sand was prevented to a large extent by the packing of grass hay, and where it was impossible to prevent it a sample unaffected by the run-in was obtained with the small caisson.

4. With the caisson close to bedrock and most of the water shut off, the bedrock was easily cleaned and tested.

5. Frequent panning and occasional washing of large samples of the tailing from the long-tom showed it to be a very efficient gold saver.

6. Frequent cleaning up and systematic shifting of the crew; check samples with the small caisson; and continual panning ahead of the shaft make undetected salting by any member of the crew, excepting the panner, impossible. Careful sealing of the shaft at night and separate washing and weighing of the first box of dirt in the morning make a good safeguard against salting during the night.

Preservation of Timber in Mining

By F. K. R. MOLL

There are four main fields in which timber is used in enormous quantities and where by natural conditions this timber is rotting extremely rapidly. Telegraph and telephone line poles, railway ties, the piles and jetties of harbors, and mine timbers last when untreated so short a time, that, if means be not found prolonging the lifetime by artificial processes, the use of iron and concrete soon may be more profitable. In consequence of this fact the preservation of timber has become more and more common in recent years in the United States. It is in mining that up to this time almost nothing has been done. Unmeasurable quantities of timber and millions of dollars are therefore lost every year.

From the year 1905 Kellog in the U. S. Department of Agriculture Circ. 49 gives the following figures on the amount of timber used in mining, (all data in cubic feet, round and sawed timber combined):

	Cu. ft.
Bituminous coal mines	103,000,000
Anthracite mines	52,000,000
Precious metal mines	29,000,000
Iron mines	15,000,000
Miscellaneous	2,000,000
Total	201,000,000

If the production in the year 1905 be taken at 69,000,000 tons of anthracite, 287,000,000 tons of bituminous coal, and 24,000,000 tons of iron, the amount of timber was 0.75 cu. ft. per ton of anthracite, 0.36 cu. ft. per ton of bituminous coal, and 0.85 cu. ft. per ton of iron ore. In the year 1912 the amount of timber per ton in the German mines was 1.0 cu. ft. for anthracite, 0.33 cu. ft. for bituminous coal (lignite), and 0.2 to 0.7 cu. ft. for iron. There is evidently no great difference. Using these units and the production of 1910 the total quantity of mine timber will be found to be as below:

	Tons.	Cu. ft.	Cu. ft.
Anthracite mines	85,000,000	× 0.75 =	64,000,000
Bituminous mines	370,000,000	× 0.36 =	134,000,000
Iron mines	24,000,000	× 0.85 =	20,000,000
Other mines			42,000,000
Total			260,000,000

This is equivalent to 7,400,000 cu. m. The German mines used in the same time about 6,300,000 cu. m. = 220,000,000 cu. ft. of timber; that is only 15% less than the American mines. Of the 260,000,000 cu. ft. of mine timber, nearly 170,000,000 cu. ft. was hardwood, and only 90,000,000 cu. ft. softwood. Among the softwoods pine ranks first with 40,000,000 cu. ft.; among the hardwoods, oak with 40,000,000 cu. ft. On the contrary in Germany only 2% of all mine timber was beech and 1% oak, nearly all the remainder was pine.

The price for mine timber is rising from year to year

and is today about 6.5c. per cu. ft. for round timber and 20c. per cu. ft. for sawed timber; an average of 8c. While the timber was formerly cut near the mines, today these forests are exhausted and only second growth round timber of small dimensions is available. Most of the sawed timber, boards, lagging, and planks must be shipped in from great distances. The United States faces now the same situation that Europe faced 30 years ago.

Slowness to Adopt Process

Compared with the annual cut of timber the amount of mine timber used in the United States is only 1%; but it should be realized, that every year four times the annual growth is cut. If only the annual growth were cut and the capital of the forests were kept constant, the percentage for the mine timber would be 3.3. More than 50% of this timber is every year lost by decay in the mines, while the percentage of timber for new work is ridiculously small. To the trained engineer it is astonishing and incomprehensible, that in spite of the knowledge of this fact, up to this time almost nothing has been done for the artificial preservation of mine timber. It is true, there is some interest in the question of timber treating even among the mining people, but if one asks: "Why then do you not begin with treating?" the answer is: "Oh, first we must try this thing, we have read and heard this and that, and some processes are offered to us, but without our own experience we cannot start with timber treating. So we have set some 10 or 20 test props and if they prove to be good, we will take up the matter."

A practical engineer however, never expects to study all problems himself and to try out all processes in his own plants. He determines first whether others have made the tests, and if he finds that they have done so he makes use of their results. In treating timber, and especially mine timber, so many tests have already been made that there is no longer any question as to what to do. It is possible that the tests now arranged may show that some new invented processes are more favorable than the old ones now in use, but I think, up to the time such tests are finished, it is safe to use the old processes of which the results have long been known. The technical journals of Germany, France, and England, where the matter of treating mine timber has long been one of great importance, contain a great number of articles giving the results of experience with a great number of timber-treating processes. It is true that even in Europe there was not much impregnation of mine timber during the nineteenth century, but since the year 1900 there has been a great change, especially among the German mine-owners, and in that country since the year 1905 no less than 100 large and small timber treating plants for mines have been erected.

Timber Preservation Important to Miners

Artificial preservation of timber is of especial importance in mines, for nowhere does timber decay as quickly, especially in coal mines. The most favorable conditions for intensive growth of the wood destroying fungi are the presence of a certain degree of heat and dampness. In most of the coal mines both the temperature and the dampness are such as to afford optimum conditions for the fungi. All other causes of destruction of timber are unimportant when compared with the decay. Wear and fire cause the loss of about 5%. Against the breakage, the consequence of crushing, squeezing, or swelling ground, it is possible to protect timber by special methods of constructing the sets. Against the damages caused by insects the best protection is to bark the timber as soon as possible after it has been cut. Against the decay the only remedy is impregnation with liquids poisonous for the fungi.

Artificial preservation of mine timber was first studied in the United States in 1906. At the suggestion of the U. S. Forest Service the Philadelphia & Reading C. & I. Co. carried out a great series of experiments. The Company placed about 1000 sets of round gangway timber that had been treated by 15 different methods, so that each method was tested by from 20 up to 150 sets. While this test marks a great step onward, it is regrettable that the number of tests was so small. This is the same mistake that the German mines made 20 years ago. With so small a number of sets for each test it is not possible to get positive results. The individual conditions of the timber, of the place where set and of the men watching the tests, may well influence to a high degree the results.

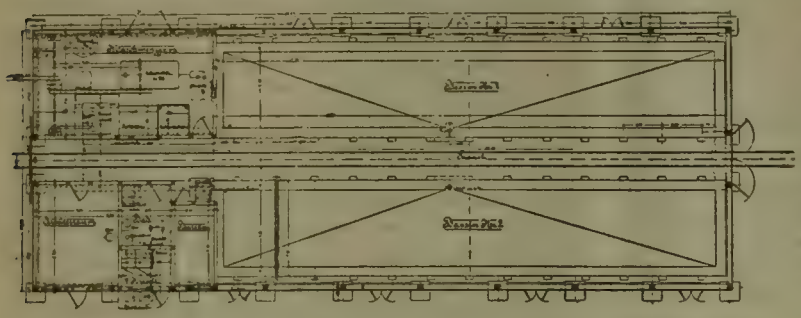
Unsatisfactory Methods Still Recommended

When studying the Forest Service *Bulletin* 107 it is interesting for the timber-treating engineer to see that processes, the uselessness of which has been realized in Germany for years, here get the certificate "not unsatisfactory." Processes such as the mere seasoning of the timber, charring it, and especially all kinds of paintings, including the so-called 'brush treatment' with tar, creosote, carbolineum, may be mentioned. In Circular No. 111, p. 11, Nelson states the disadvantages of brush treatments in the following words: (1) the difficulty of completely covering the timber and filling all checks and cracks; (2) the very slight penetration secured. The subsequent checking or opening of the timber may often allow disease to pass through the shallow exterior band into the interior wood. "And yet only one passage before," he says, "for small individual operators who cannot afford the cost of a large plant, brush treatments are feasible and economical." Testing this by the long experience of European administrations and private concerns, it seems to be a dangerous error. Again and again it was found in tests that were not based only on 2 or 3, or even 20, but on thousands of ties, poles, and props, that brushing the timber not only is of no advantage, but may even be a great disadvantage if the cost is greater than the prolongation of life.

Experience with the open-tank system has been as good or even better, as Mr. Belson shows. The prolongation of the life of mine timber in the tests was remarkable. The question will be, if the economic result, too, will be

good. That depends on the cost of the antiseptic. Using a solution of chloride of zinc or commercial creosote the impregnation was without any doubt to a certain degree economic.

The investigations of the Forest Service did not touch the matter of the influence of the impregnation on the health of the workman and miners. That is regrettable, for in Europe, where now more than 250 mines use treated timber, much trouble has been caused by the use of inappropriate antiseptics. Especially creosote, one of the most common means for treating timber, and that even in the tests of the Forest Service gave the best technical results, has been almost entirely abandoned in the European mines because of its marked influence on



OPEN-TANK PLANT FOR KYAN PROCESS.

the skin and eyes of the miners and the increase in the fire risk.

In the following pages I shall deal more especially with the experience of European mines. The engineering journals of Germany, England, and France contain many articles on timber treating in mines, but since more than three-fourths of them are written by persons interested in some way in the production and the sale of special compositions for impregnation, I prefer to use in this paper data collected from the mines through direct correspondence or personal inspection.

History of Process

Information on preserving mine timber before 1910 is rather scanty. The first reference I found ('Franklin's Journal,' 1831) relates that in 1831 a French engineer, Bréant, read a paper on wood preservation and showed a collection of impregnated wood before a circle of mining engineers pointing out the great importance of his invention to the mining industry. Real impregnation seems first to be executed with creosotnatron. This was at a time when, in mining, artificial protection of wood was not thought of. This may seem strange at first sight, the more so since creosotnatron has been used nowhere else. Contrary to the custom at anthracite mines, in lignite mines the wood is worked up at the mine to recover, if possible, paraffin. One by-product, and a very troublesome one, is creosotnatron, which is often used for fuel, although this use is difficult because of the high percentage of caustic soda lye. Nor can this be turned to waste in streams. Thus, curiously enough, preservation of timber was not begun so much in order to preserve the wood, but to get rid in the cheapest way of a by-product which otherwise was difficult to dispose of.

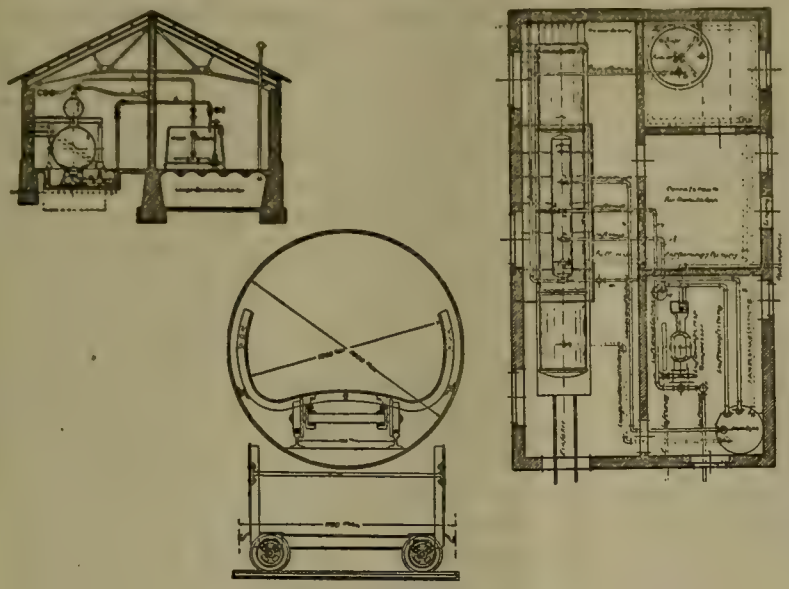
From 1890 to 1900 a number of mines were reported to soak their mine timber in hot tar or salt solutions. But until 1900 only desultory trials and proposals occurred without any connection or system. Doubtlessly wood has been preserved in mines far more often than might be supposed from the scanty literature, but certainly the question of preservation was not recognized as of general importance in mining before 1900. Then the conviction began to gain ground that economical reasons demanded preservation of wood for mining purposes as well as in the case of telegraph and railway uses. Establishments were erected and investigations on different questions connected with preserving mine timber came so rapidly that it is nearly impossible to quote them here chronologically. What preservation has become for mining in the past 14 years and which experience has been obtained in this time may, however, be shown.

What Is Mining Timber?

At first it is necessary to answer the question, what is to be understood under the term 'mining timber'; a question which will be answered rather differently according to who is asked. At a mine using the timber, the answer would be: mine timber in the narrow sense of the word is all timber serving for construction in the mine, chiefly the timber for pillars, props, slabs, and the ties for the mine railways. This wood is destined to keep the rooms of the mine open, to secure against roof falls and walls slabbing off, and to help win the minerals. Mine timber in the wider sense is all other timber employed underground and above ground, as in shafts, the sheds over the shafts, storehouses, cooling towers, and other buildings. Contrary to the general opinion of wood owners, mine timber is far from being wood useless for other purposes. In fact, it comprises many different sorts and classes. Duration of wood is not always the deciding factor. The more intensively a mine is working, the shorter the continuation of work at one spot will be, and it may occur that a place will be abandoned or filled with waste only a few days or a few weeks after the starting of the work. This case, however, is exceptional and is only mentioned to point to the fact that, besides solidity, other properties of wood, such as the light weight, cheap price, and above all 'warning faculty,' are not to be neglected. In former times all over the world oak was considered the best wood for mine purposes. Yet with the continual rise in its price, it has more and more yielded its place to coniferous wood, and in the United States the soft wood now constitutes nearly one-third of the mine timber. Surely oak wood is durable, yet its price is high and the weight twice that

of pine. The 'warning faculty' of pine, too, is far better than that of oak. For these reasons the use of coniferous wood, and especially pine, is increasing from day to day.

The total value of mine timber amounts to about $21,000,000 annually in the United States (in Germany, $20,000,000; Austria, $3,000,000 for 45,000,000 cu. ft.). But only a few years since the mines have begun to consider the question of wood preserving, to decrease somewhat the immensely increased demand. In the year 1904 there were in the mining district of Dortmund, Germany, 16 mines which treated wood, and 25 others that had made trials. About 1903 the Silesian Mine Timber Impregnation Co., Ltd. (Wolman system), entered the field, and since then this Company has erected over 30 plants in Silesia alone. It will be helpful to review some of the experiences of the mines.



IMPREGNATION PLANT, WOLMAN SYSTEM.

Tar products, mixtures of carbolineum and chloride of zinc, creosote oil and chloride of zinc, carbolineum and solutions of 'waste salts,' pure creosote, and many other oils won from tar—offered often under most quaint names and at prices by far exceeding the real value ('Carbolineum Avenarius,' 'Barol,' 'Cruscophenol,' 'Carburol,' 'Exsiccator') were all tried at various mines. Not one of these won favor. The extreme improvement claimed for some of these oils rested upon some secret addition and the promises of advertisements failed to be made good. Salts suspended in the oil (such as chloride of zinc and chlorine gas in 'Carbolineum Avenarius,' copper salts in Nördlinger's 'Barol') are entirely useless, as has been proved beyond question by numerous impartial investigations. In all cases the price was far too high for mine purposes ('Carbolineum Avenarius up to 32c. per gallon). Many mines, too, are able to produce creosote from their own by-products and at a price of 4 or 6c. per gallon.

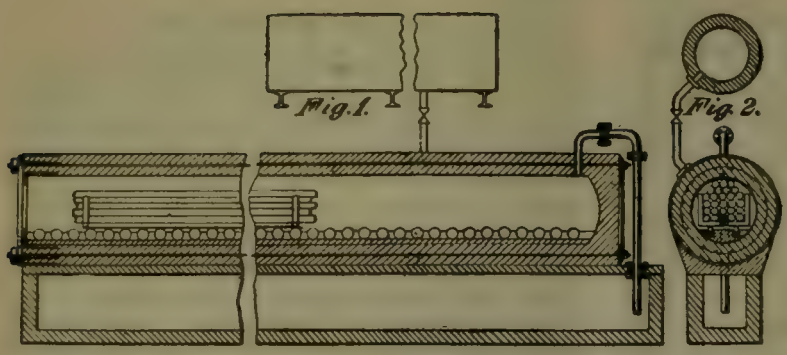
Salt Solutions Most Used

The technical methods advocated were painting (brush system), open tank, and cylinder treatment. The brush system proved to be entirely worthless. Open-tank systems, provided that the timber is soaked long enough and that the oil is hot, give better results. Tanks for this process were erected at numerous mines (a great number of them by Cruskopf), but only one mine is today using the process with creosote or cruskophenol; all others (39 in Germany) use now salt solutions.

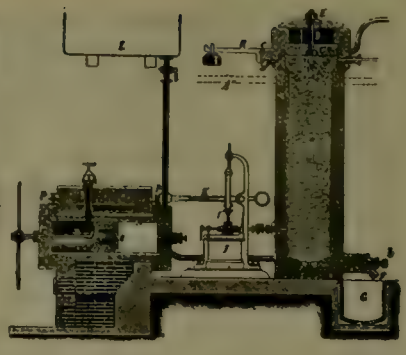
Impregnation in the cylinder has proved the best method, provided that the oil is cheap enough, as when obtained as a by-product at the mine. That is the case with Lothringen mine (Gehrte, Westphalia), that obtains the oil at a cost of 3c. per gallon. All reports show that the brush system is worthless, the open-tank system gives but little effect, and only the cylinder process gives good results. The chief condition, however, is the production of the creosote by the mine company itself.

If only prolongation of the duration were the point of interest, creosote might be called a very good antiseptic. In the course of time, however, so many unpleasant features have developed, just as with the similar creosotnatron, that a great number of mines have abandoned creosote. Stens, a Royal mine inspector, as a result of his experience as director of one of the greatest mines, enumerates these disadvantages as follows: "Creosote has a piercing, disagreeable smell; many men decline to work where wood preserved with it is employed; furthermore, creosote means a considerable augmentation of the danger of fire; where the men are sweating at the work, which in mining is the rule, the oil causes very disagreeable diseases of the skin." The ingredients, evaporating from the oil, affect the eyes. The timber becomes very heavy. An impregnation of only 6 lb. per cubic foot means, with pine wood, an increase of weight of about 20%. These statements were confirmed by a communication from the Belgian anthracite mines at Mariemont, which used creosote since the year 1899. In spite of the very satisfactory results, considering economy, the mine had to stop employing this process on account of the effect on the workmen. The same happened with the creosotnatron, used for more than 50 years in German and English mines. Most of these mines in the last years changed over to impregnation with salt solutions.

The influence of salt solutions on the duration of wood in the mines has been long known. The good preservation of wood in copper and iron mines where they were



CYLINDER OF REINFORCED CONCRETE, MOLL PATENT, FOR KYANIZING WITH PRESSURE.



BRÉANT IMPREGNATION CYLINDER.

traversed by the so-called 'cement waters,' that is, solutions of the vitriols made by a conversion of copper and iron pyrite, attracted attention long before a regular intended impregnation was thought of. In the Spanish copper mine, Rio Tinto, timber has stood since the times of the Romans. The first artificial impregnations were made with the salt brine and abraum salts of salt mines. Aitken in 1893 erected two iron tanks at the Niddrie mine in Scotland to impregnate timber with a concentrated solution of kitchen salt and magnesium-chloride. The Eschweiler Mine Union (Germany) has used the Burnett process since the year 1890, with chloride of zinc. This mine, however, was not entirely content with the results.

It may seem strange that the old methods of Boucherie, Kyan, and Burnett, well proved since the year 1850 by the railway and telegraph administrations, remained almost entirely neglected by the mining companies. As to chloride of zinc, the reason of this fact may have been the low efficiency of this salt. The Boucherie method met with other difficulties, mine timber being delivered to the mines (on account of the high freight) dressed and well seasoned, while the process is intended for use with fresh cut wood. The kyanising firms at that time had no plants in the mining districts. Thus it came that in mining, impregnation at first went its own way, without connection and totally neglecting the experiences of other industries.

Many mines use salt brine (Morl in Saxony, Hagenbeck, Humbold Neuglücker Verein, and Wische in Westphalia), others tried the processes of Hasselman, Viscal, Aczol, Wiese, Höttger, and Haskin. Most of these processes have completely disappeared and none are now of great interest. There was only one of the new processes based on the studies of the Austrian engineer named Malenkowicz, the Wolman process, that has won a leading position in mining. Wolman's metal-salt mixture processes, by skillfully measuring the single ingredients, has won position among the best processes for timber treating. The base of these mixtures is either the well known sodium fluoride or the bichloride of mercury.

To look closer at the demands, which can and must be met today by any successful method of preserving wood, especially mine timber, and to see how far the various more important methods suit these demands, they may be summarized as below:

1. Preservation is to prolong the duration of wood. For this purpose the substances employed must be injected into the wood in efficient quantity, either taking small quantities of highly effective substances or great quantities of little effective substances. The quantity of feeble salts, however, is limited by the quality of the wood. Salts can be injected in liquid form only, and pine wood cannot absorb more than 22 lb. of liquid per cubic feet. The more the concentration approaches the point of saturation of the solution, the more difficult this becomes. When using kitchen salt, 6 lb. of salt per cubic foot of timber should be used. That would mean a solution of at least 27%. According to practice it is far better to work with strong effective salts, of which small quantities of 1 lb. at most is sufficient. Such salts are sublimate, fluoride of sodium, and fluoride of zinc.

2. Economy is based upon the efficiency and on price. As to the efficiency it is difficult to find a fit scale. Often the numbers of cultures of fungi on gelatin and other substances are taken as a measure for the efficiency. Practice must, however, decide. Every culture works with a certain fungus, while in every mine, mixtures of most different fungi are found upon the wood. It is necessary to render the wood prophylactic, that is, to impregnate before putting in the timber, and to protect it against the strongest enemy to be expected. The methods used by the telegraph administration and proved by 50 years' experience yield the following succession as to duration and economy (based on the prices of today): Kyanizing and creosoting; burnettizing with chloride of zinc; boucherie process with sulphate of copper. Wolman's process with sodium fluoride may be ranged near the kyanizing process.

3. The antiseptic must not increase the combustibility of the timber, nor must it have a bad influence on the mine workers. The disagreeable effects of creosote have already been discussed. A mine director plainly said shortly: "Luckily these creosoted instruments of torture are put in only a few mines." It would be equally bad to raise the danger of fire in coal mines, great enough without that, by employing the oil. Creosote may therefore be dropped from further discussion.

4. Salt solutions should be made to penetrate all parts of the wood, which can be impregnated, at least the whole sap. Where one cannot work with cylinder, the timber should be immersed long enough in an open tank. When the wood has been well seasoned this will be sufficient in many cases, provided that the solutions are effective. Using sublimate (Kyan's process), the solution may be used cold. Wolman's fluoric salt mixture should be used only hot. If great quantities of timber are to be preserved, it is at any rate better to work with a cylinder with vacuum and pressure. The cylinders are constructed of iron or of armed concrete (for sublimate).

5. The antiseptic must not destroy the wood. This demand seems absurd, and yet several times methods of preservation have been employed for mine timbers, which severely affected the wood. I name as the most important in this respect the creosotnatron, the Aczol, the Viszal, the kulba (sodium zincate), and the Hasselman process. In the trial cellar or the Petri dish these processes have given excellent results, for the wood was destroyed to cellulosis, and cellulosis is not attacked by fungi. But if the fibres of the wood have lost their contact, the timber in the mines is soon destroyed.

From all the hundreds of salts proposed for preservation of mine timbers, only two have proved their fitness at all, and this may be considered the best according to the present state of knowledge. These are the sublimate (bichloride of mercury) and the sodium fluoride. The latter is, on account of various reasons, not profitably employed pure, but with other salts. These mixtures have been studied for years by Wolman, and their composition has been so perfected that any difficulties arising of free acids is prevented.

Sublimate and Creosote

Sublimate usually is employed in the open tank process. The timber is immersed in big concrete tanks for a suitable time, the solution being generally of 0.⅔%. The invention of cylinders of armed concrete, allowing the impregnation under vacuum and pressure (Moll construction), and the mixture of sublimate with other salts preventing the corrosion of iron cylinders by the solution (Wolman invention), afford great advantages over the old process as devised by Kyan.

The method of impregnation in cylinders may be briefly described as follows: At first the wood which is to be impregnated is sufficiently seasoned. After this it is put on small cars and carried to the impregnation cylinder. The dimensions of this cylinder, of course, are adapted to the wants of the mine as regards the length and the thickness of the timber. The cross-section, as a rule, is about 6 or 7 ft., which gives good working conditions. The length varies from 20 to 150 ft. The figure shows an establishment of the Silesian Mine Timber Impregnation Co., Ltd. (Wolman system). Note especially the small cylinder above the big one. When the lye is forced into the wood this small cylinder is filled with the solution and is connected with the impregnation cylinder. As the lye passes into the wood the latter is always replaced by influx of solution and the surface of the wood does not become exposed. The storage tank of the solution is arranged in the basement of the plant, with the dissolution tank above it. This must be of considerable dimensions on account of the great quantities of solution which are needed.

After the wood has been brought into the cylinder it is closed and as high a vacuum as possible is produced, which is kept on for one hour. By this means the wood is intensively seasoned. Then the solution is sucked from the storage tank into the cylinder by means of the same vacuum. As soon as the cylinder is filled, pressure is produced by means of an air-pump. The temperature of the solution is kept at 60 to 70°C.(180°F.). Fast at first, then more and more slowly, the wood absorbs the solution. The pressure is regulated according to the sort of wood, being between 4 and 8 atmospheres (60 and 120 lb. per square inch). After two or three hours the process is finished. The door of the cylinder is then opened and the wood brought out and seasoned. By evaporating the water the salts are fixed to the fiber.

Some general remarks may be appended as to the costs of mine timber treatment. The impregnation surely needs not to be as intensive as that necessary for ties, mine timber serving in most cases but a few years. But as untreated wood seldom lasts longer than one year, even a prolongation of 3 to 5-fold of the original duration is an extraordinary gain. This prolongation is certainly to be obtained with a quantity of 1 lb. of sublimate or 12 lb. of the sodium fluoride mixture to 25 cu. ft. of timber. The pound of sublimate costs today 50c. and the pound of the salt mixture 5c. Regarding the costs for heating the solution, for amortization and interest, working capital, and wages, and all other items, these may safely be taken to not exceed 5 to 6c. per cu. ft. of timber. These statements show clearly that the preservation of mine timber on an economic scale is today possible, and that the use of impregnated timber in mining is a necessity for personal and national economy and for the conservation of the valuable forests, that under the present system soon will be exhausted.

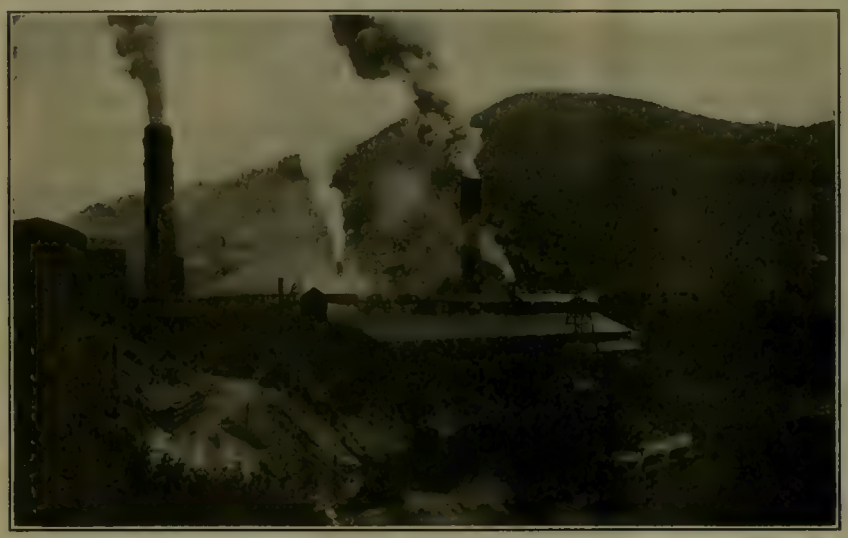
Gold output of the Crown Mines, Johannesburg, in November, totaled $1,238,000 from 199,000 tons of ore. The profit was $480,000. There were 660 stamps dropping for 27.25 days. During the third quarter of 1914 the following resulted: ore crushed by 660 stamps and 24 tube-mills, 613,000 tons; gold recovered, 183,325 oz.; value per ton, $6.34; working cost per ton milled, $3.72; profit, $1,364,000. There were 12,682 natives employed.

The Frontino & Bolivia property, Bolivia, produced $423,000 from 33,876 tons of ore during the year ended June 30, 1914. This was a small increase over the previous year. The profit was $31,700. Reserves in the Silencio mine are 16,800 tons assaying $21 per ton. A new pump is being installed on No. 13 level, and sinking is to be resumed.

Improvements at the Trail Smelter, British Columbia

*This plant is operated by the Consolidated Mining & Smelting Co. of Canada, and in the year ended September 30, 1914, it treated 374,771 tons of mixed ores, yielding gold, silver, lead, and copper worth $6,000,662.

Expenditure on equipment at the property during the year was $571,207. Of this amount, $482,134 was spent in improvements to the smelter. This was mainly as follows: Rebuilding the lead plant, including placing two Wedge roasters, having a capacity of from 85 to 95 tons per day each; conveyors and automatic scales for handling ore from storage to the roasters, and for handling pre-roasted product from roasters to sintering pots; three new lead blast-furnaces and extensions to building, with crane for handling receivers and by-products such as matte; a Cottrell plant for clearing the blast-furnace gases of lead fume; flues connecting the blast-furnaces with the Cottrell plant; and new charge-cars and some small equipment for the lead-sampling mill.



TRAIL SMELTER, BRITISH COLUMBIA. THE COTTRELL PLANT HAS CONSIDERABLY REDUCED THE LARGE FUME LOSSES SHOWN.

Alterations to the copper plant included rebuilding of three of the five blast-furnaces and increasing the dimensions of two of them; building of a new smoke-stack; repairs to the flues; and installation of a crane in the copper furnace building, and rebuilding of the launders leading to the slag dump.

Improvements in the blower-room were the installation of an additional blower having a capacity of 40,000 ft. of air per minute; extensive repairs to the blower-room on account of the rotting of timber foundations, floors, and retaining walls, all of which have been replaced with concrete; rebuilding of the fire-protection system was also necessary during the year; and small expenditures were made on tracks, on tunnels for recovering ore from storage, and on extra locomotives for charging the furnaces.

The objects of these alterations and improvements were to increase the capacity of the plant, to increase recoveries, and to decrease costs of operation.

The lead plant formerly handled a considerable tonnage of high-grade clean concentrate, comparatively low in sulphur and free from zinc, which was supplied mainly from the St. Eugene mine. With the depletion of the St. Eugene mine, it has been necessary to replace the tonnage, to a large extent, with ore of lower grade and of a much more refractory nature, largely from the Sullivan mine; and carrying more sulphur and requiring more capacity for roasting and furnacing in order to produce an equal tonnage of lead.

In the roasting plant, particularly, the seven Godfrey roasters with which the smelter was previously equipped, had a capacity of only 25 tons per day each of Sullivan ore; the two Wedge roasters, just installed, have a capacity each of from 85 to 95 tons per day, and are costing at present about 50c. per ton less to operate, the saving being mainly in fuel and firing.

The installation of conveyors handling the ore to and from the roasters will still further reduce costs of operation of the roasters, by substituting mechanical equipment for manual labor.

The costs of operating the Heberlein sintering plant have already been materially reduced by the substitution of mechanical appliances for hand labor, which alterations were made last year.

The building of new lead furnaces was made necessary by the condition of the old ones, which had been in operation for a long time, and it was considered advisable in rebuilding them to place them farther from the copper plant, in order to allow for any necessary extensions to the copper plant; also to allow for better arrangements for charging and handling the products.

The installation of the Cottrell plant was necessary on account of large losses in fume from the blast-furnaces. The flues and Cottrell plant are now saving approximately eight tons per day of material high in lead, a considerable portion of which was previously lost.

Improvements to the copper plant were made necessary by the wearing out of jackets on the old furnaces.

*Abstract from annual report of general manager, R. H. Stewart.

In rebuilding, two of them have been increased in size from 300 to 420 inches in length, and from 42 to 50 inches in width at the tuyeres. The enlarged furnaces so far show an increase in smelting capacity of from 60 to 80% over the older ones. This increase in capacity will result in a proportionate decrease in cost of labor, and probably in a decrease in cost of coke per ton of ore smelted.

Generally speaking, it is thought that the changes made in the smelter during the past two years will result in sufficient saving in costs of operations and recoveries to pay for themselves within the next two to three years' operation.

Chemical Problems in Germany

*As a result of the war, German chemists have been confronted with a number of very important technical problems. Some of these problems are old ones that have been rendered acute by the war's interference with commerce, while others are newer and are all the more difficult because little attention had been given them before the opening of hostilities. The chemists are co-operating in a marked manner to furnish substitutes for gasoline and rubber.

As regards the supply of gasoline, Germany has in the past depended almost entirely upon foreign markets. The greatest quantities of this important fuel were imported from Russia, Galicia, the Dutch East Indies, and especially Rumania. Normal imports at this time can be had only from the last-named country.

It has been necessary, therefore, to turn to substitutes, the most important of which are benzol and alcohol. Benzol is a by-product of the manufacture of coke, and the German production amounts to about 160,000 tons per year, of which about 60,000 tons are used for chemical purposes, especially in the dye and color industries. About 100,000 tons is available for fuel purposes. As the consumption of gasoline in Germany amounted to 179,800 tons in 1912, it will be seen that a considerable part of the gasoline can be replaced by benzol.

Benzol possesses valuable qualities as a fuel, containing 9560 heat units per kilogram (2.2046 lb.), and being only slightly inferior to gasoline in this respect. A disadvantage in winter is the high freezing point. Benzol freezes above zero (32°F.), and then must be raised to about 7° (44.6°F.) before it will melt. Efforts are being made to overcome this disadvantage by adding nitrogen. There is no danger of freezing if alcohol is added, and mixtures of benzol and alcohol have proved very successful. There is no shortage of alcohol for motor purposes. Toward the end of August the available supply in Germany amounted to more than 26,000,000 gal. On account of complications arising from the war, the average distillation was reduced by 40 per cent.

The by-products of the distillation of brown-coal tar may also be considered as substitutes for gasoline. The number of substitutes from all sources would be considerably increased if carburetors could be adapted to other fuels than the ideal gasoline. As progress is being made in this direction the shortage of gasoline becomes less important.

Problems arising from the shortage of rubber are much more difficult than those arising from the motor-fuel situation. This is already shown by the increases in rubber prices and by the strict military regulation of its use. The importation of caoutchouc (India rubber) has been interrupted, and the synthetic production of this valuable material was neglected before the war. The necessity for a substitute exists today, and the scarcity of natural caoutchouc will focus attention on the development of a synthetic process. Several satisfactory substitutes have been evolved by combining acetone and benzol products with caoutchouc. A certain supply of caoutchouc can be maintained by the manufacture of regenerated caoutchouc from scrap rubber. This regenerated-caoutchouc industry is highly developed, and large stores of old rubber exist.

The problem of providing the industries and agriculture with nitrogens is a serious one. The importation of Chile saltpeter has been interrupted, and the country is short nearly 800,000 tons of this material as measured by the consumption in 1912. It is estimated that one-third of this quantity is used in manufacturing and the remainder in agriculture. It is used in the production of nitric acid, which is so important in the manufacture of explosives. The existing stores of saltpeter have to serve, in the first place, the purposes of the army, and a substitute for a half million tons for agricultural purposes must be supplied. Sulphate of ammonia, a by-product of coal distillation, is the most productive source of nitrogen that Germany has, and as a fertilizer is a formidable rival of Chile saltpeter. It is though that a larger percentage of nitrogen in the form of ammonia can be obtained from coal than has hitherto been done. The synthetic production of ammonia may be of assistance in furnishing a supply of combined nitrogen, and, finally, the manufacture of cyanamid, a mixture of atmospheric nitrogen and calcium carbide, will supply the country with an important nitrogenous fertilizer.

The imports of jute have been cut off by the war. This fiber is needed in the manufacture of bags, which are, of course, in great demand. Cellulose is used in making a substitute for jute, and a kind of paper is manufactured out of which bags are made. 'Textilose,' a composition of paper fiber and cotton fiber, is being considered as a bagging material. American resin in large quantities is needed for the tightening of fibers in the manufacture of paper. For this purpose there is no satisfactory substitute.

*Report of deputy consul-general Daniel J. Waters, Berlin, November 21.

EXTRACTION at the Cam & Motor mill, Rhodesia, is improving, and during November, 11,748 tons of ore yielded $86,000, with 73% recovery.

DISCUSSION

Readers of the MINING AND SCIENTIFIC PRESS *are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.*

Shall the Institute Express Opinions?

The Board of Directors of the American Institute of Mining Engineers being divided in opinion as to the advisability of adoption of the proposed amendments to the constitution designed to remove the present restriction on any expressions of opinion by the Institute, appointed a special committee to formulate the arguments for and against them. The committee consisted of E. Gybbon Spilsbury, F. Lynwood Garrison, Sidney J. Jennings, James F. Kemp, Albert R. Ledoux, Rossiter W. Raymond, Thomas T. Read, and Horace V. Winchell.

The report submitted was as follows:

ARGUMENTS IN FAVOR

1. The Institute with its membership of 5000 is the recognized organization of the mining profession, and should be able to take action as such. The limitations placed on the activities of the Institute by its constitution are a denial to its members of liberty of action and judgment, and thus in conflict with the essential principles of democracy.

2. The Institute has become so strong and so truly national in its make-up that whatever necessity once existed for guarding against its passing into the control of a small coterie which might use its influence for improper ends, has long since passed away.

3. There is no reason to suppose that the membership of the Institute will be less competent to deal with its problems in future years than at the time the constitution was drawn up. It is reasonable to assume that situations may arise in which the course of action laid down in past years will not be the best to follow.

4. There is no reason to suppose that the Institute will at once abandon its successful policy of 43 years. All that is proposed is to permit the Institute to take action as a body in the rare instances in which it is clearly desirable to do so.

5. The Board of Directors must, according to the constitution, represent every section of the country. It is made up of responsible men who give to Institute matters such careful consideration that it can be safely assumed no hasty action on any matter will ever be taken.

ARGUMENTS AGAINST

1. The certificate of incorporation states the purposes of the Institute, namely: "to promote * * * by means of meetings for social intercourse and the reading and discussion of papers, and to circulate by means of publications among its members the information thus obtained, and to establish and maintain a place of meeting * * * and a library of books * * *:" These functions are specific and were intended to be exclusive. Other means, equally praiseworthy, are excluded, if they tend, as shown below, to impair the effectiveness of these.

2. The success of the Institute as a forum of free discussion would be impaired by making it a tribunal of decision.

3. On the important questions likely to arise, the members are certain to be divided; and the defeated party will become less hearty in its loyalty and co-operation.

4. The voting membership comprises three nations; and is therefore not a suitable body to decide questions of policy, etc., affecting one nation only.

5. Every man who joins the Institute is entitled to the assurance that its influence will not be used for or against any scheme or proposition affecting his views or interests.

6. The prohibition which these amendments seek to remove was put into the former constitution and repeated in the present constitution as the result of long experience. It has worked well for 43 years, and it should not be removed without the provision of careful safeguards against abuse of power. If there are certain acts now forbidden, which would be useful and unobjectionable, then the certificate of incorporation and the constitution should be amended by specifying such acts. Let us put a gate where it is really desirable to go through the fence, but not tear down the whole fence.

ANOTHER ARGUMENT FOR

The Editor:

Sir—The mining industry of the United States is second in importance to that of agriculture, and represents from mining and metallurgical establishments an annual product that amounts in value to $4,600,000,000. There are engaged in this industry 2,300,000 men, and there are probably depending upon it for a living, something like ten to twelve million people. It is safe to assume that a majority of the men who direct and control this tremendous industry are members of the A. I. M. E. and that the Institute is the only organization of which this may be said.

Few of its members realize that the Institute is today prohibited by a drastic clause in its constitution from exerting any influence for the direction, protection, and fostering of this vast and fundamental constituent of our civilization. Article VIII, Sec. 2, of the constitution reads as follows:

"The Institute shall not assume responsibilities for any statements of fact or opinion advanced in the papers or discussions at its meetings. Neither the Board nor the Institute shall officially approve or disapprove any technical or scientific opinion, or of any proposed enterprise which is outside of the management of the meetings, discussions and publications of the Institute, and the conduct of its business affairs by the Board of Directors."

And Sec. 3:

"Special committees may from time to time be appointed by the Board to make investigations and prepare reports for presentation to the Institute, but no action shall be taken binding the Institute for or against the conclusions embodied in any such reports."

It is now proposed to amend these sections by striking out part of the inhibiting clauses of the two articles, so that they will read as follows:

"Sec. 2. The Institute shall not assume responsibilities for any statements of fact or opinion advanced in the papers or discussions at its meetings."

"Sec. 3. Special committees may from time to time be appointed by the Board to make investigations and prepare reports for presentation to the Institute."

Some objections have been raised to this course, chiefly on the ground that it places too much responsibility in the hands of the Board of Directors. In reply to this objection it is submitted that no organization composed of a large number of individuals or of diverse interests, can be properly conducted without delegating to the representatives of the members on a board of directors, sufficient power properly to conduct, control, and direct the policy of the organization as a whole.

The question now before the members of the Institute is therefore primarily one of policy. Shall it, or shall it not, be the policy of the Institute to protect and foster this industry and those engaged in it? The certificate of incorporation of the Institute states:

"That the purposes for which this corporation is to be formed are: To promote the arts and sciences connected with the economic production of the useful minerals and metals and the welfare of those employed in these industries by means of meetings for social intercourse, and the reading and discussion of professional papers, and to circulate by means of publications among its members the information thus obtained; and to establish and maintain a place of meeting for its members and a hall for the reading of papers and delivery of addresses, and a library of books relating to subjects cognate to the sciences and arts of mining and metallurgy."

It is furthermore submitted that although the Institute has done a vast amount of good in furthering the objects above set forth, it has fallen far short of the possible usefulness it might have achieved had its policy not been hampered and restricted by the constitutional provisions it is now proposed to amend. It should be pointed out that when the Institute was organized in 1871, and for perhaps 25 years following that date, the desirability, or necessity, for an organization that had the power now sought, was not so evident as at present.

Within recent years it has become more and more evident to those most closely in touch with mining matters throughout the whole United States, that if these interests are to be wisely conserved and directed it must be done by some such organization as the A. I. M. E., and that if the Institute fails to realize its responsibility and opportunities in this respect, some other organization, perhaps less well qualified, will arise and do it. To be more specific, it is not intended that the Institute, through committees or otherwise, should ever stoop to legislative lobbying in order to achieve its ends, but it should be free, when occasion offers, to advise, recommend, and point out, as a body of experts, what are the needs of the mining industry, so that efficiency, economy, and national well being may be thereby attained. At the present time there is absolutely no other organization which is so well fitted to do this. Responsibilities in life must not be shirked by organizations of individuals such as the Institute, any more than by individuals themselves.

The responsibilities that would be thrown upon the Board of Directors of the Institute, should these amendments be adopted, would probably be no greater than those now carried by the Board of Directors of the American Society of Civil Engineers, which has a membership of over 7500 and the highest qualifications for entrance of any of the great engineering societies. The A. S. C. E. has no clause in its constitution prohibiting its directors from acting upon public questions, and its policy is, and I believe always has been, never to shirk responsibilities of this kind. That the men whom its members have elected as directors are able, broad minded, and of sound judgment, is attested by the remarkable growth of the Society in the past 20 years. Its membership has increased in that period from 1733 to 7635, and its material resources from $60,000 in 1894 to $650,000 in 1914. Surely the A. I. M. E. is just as capable of selecting its directors and has just as many able men to draw from.

Has the Institute grown to manhood, or must it still be hampered by the swaddling clothes of infancy and irresponsibility? Is it still to be an organization solely for the purpose of publishing papers and holding social meetings; or a great body of experienced and capable mining men, truly representative of a great national industry, anxious for its welfare and ever ready when called upon to lend a helping and directing hand? If it now fail to recognize and accept its responsibilities it cannot complain if others less competent undertake to do what it neglects, and a great national industry suffer in consequence.

Thoughtful and well informed men must recognize that the most important need of the present time is that the great industries be wisely guided. Governmental interference in business is becoming more and more frequent; this condition must be accepted as a fact, for it

cannot be successfully opposed. It will be for good or ill, accordingly as it is directed. Are the mining engineers, from timidity or a childish policy, to sit still and let the mining industry become a football of politics, the butt of labor unions, and continue under the spell of an archaic mining law? Engineers surely desire neither to engage in politics nor to antagonize labor, but this organization, representing the most and best elements of a great industry, must be free to speak when occasion demands and be in a position to lay before the public what is known to be the truth and believed to be best for the interests of all. The importance of this matter cannot be overstated, and its consideration may not safely be delayed. If the Institute is not to progress and assume the responsibilities of a vigorous maturity, and no greater than those entrusted to the American Society of Civil Engineers, it surely will revert to senility that has but one end.

F. Lynwood Garrison.

Philadelphia, October 29, 1914.

Rhythmic Precipitation and Colloidal Ores

The Editor:

Sir—The paper by Mr. Creighton and the editorial comment elsewhere in this number are timely, and remind the readers of the *Mining Press* of one of the live subjects of thought today among students of ore deposits. The importance of colloids and their applications to certain forms of ores seem to have been brought out among the first by F. Cornu, who published a paper in March 1909, in the *Zeit. für prak. Geologie*, p. 81, with the translated title of 'The Significance of Colloidal Bodies in the Oxidized Zone of Ore Deposits.' Various amorphous minerals were cited in illustration, of which limonite is, of course, the most frequently present in the iron hat. Mr. Cornu considered that colloids or 'gels' (gelatinous bodies) were limited to the oxidized zone, so far as his observations extended. The elaboration of this subject was taken up at the International Geological Congress in August 1913, at Toronto, by Paul Krusch, whose paper, delivered and printed in German, has the translated title 'Primary and Secondary Ores, Especially with Regard to the Colloid (Gel) Ores and those Rich in Heavy Metals' (proceedings of the Congress, p. 275: translated by Adolph Knopf and printed in the *Mining and Scientific Press*, September 13, 1913). For some years before the delivery of this address, Krusch had been giving attention to the distinctions between primary and secondary ores, as one familiar with his writings readily observes, and had directed his attention in consequence to colloids. He became especially impressed with their importance in the hydrated silicates of nickel, which constitute one of the sources of this metal. He was led to the conclusion that these ores, of no definite crystal form, developed in the alteration of peridotites as 'gels.' Further reflection convinced him that other primary colloids might be precipitated in veins and far below surface conditions, but he realized that acidity in solutions operates unfavorably to the formation of colloidal ores. We have learned, however, from the observations of W. H. Emmons and F. F. Grout of the University of Minnesota, and of their student E. T. Hodge, that descending acid waters soon became alkaline, whereas ascending waters, as was long known, are almost, if not quite, universally alkaline. To this extent ascending waters are not unfavorable to 'gels.' Krusch reminds us that gelatinous silica has been maintained for several years at temperatures of 80 to 100°C., and that sulphide 'gels' may develop above 100°C., but that their tendency is strong to crystallize. We infer, however, that colloidal sulphides could separate in uprising alkaline waters at temperatures as high as 100°C. We are also impressed with the fact that quartz veins might begin as gelatinous silica up to this temperature and that they might contain sulphides likewise colloidal, but that in time all might become crystalline. The importance of the experimental work of Messrs. Hatschek and Simon,* referred to in the editorial, now appears. The wonderful banding of precipitated metalliferous compounds in 'gels' of various sorts reminds us of agates and to some extent of banding in quartz veins. Nevertheless, we are reminded that opaline or even chalcedonic quartz is rarely seen in mineral veins such as we mine, but that crystalline quartz is the form of silica with which we specially deal. The banded structure of the last is, however, strongly reminiscent of some of the beautiful figures given by Messrs. Hatschek and Simon in their paper before the Institution of Mining and Metallurgy. Certain white and amethystine quartz veins banded with cloudy black argentite which one can observe underground at Pachuca and Guanajuato, Mexico, recall to mind most strongly the cases of artificial precipitation.

In the case of other banded veins such as the Freiberg types, with their alternations of sulphides, barite, calcite, fluorite, and quartz, or the wonderfully developed ones at the Enterprise mine, Rico, Colorado, as beautifully figured years ago in the *Trans.* of the American Institute of Mining Engineers by T. A. Rickard, and in which quartz and rhodochrosite alternate with zinc-blende and rich silver minerals, we cannot so well infer an original colloid condition. We know of no colloid forms of some of the components, at least as yet.

A recent contribution of Messrs. C. F. Tolman, Jr., and J. D. Clark in *Economic Geology* for September last, describes the precipitation of the chalcocite molecule in finely divided colloidal form from solutions containing an excess of hydrogen sulphide, on the escape of the gas. The colloidal form, however, quickly passed to the crystalline, but the reaction possessed no features incompatible with conditions in uprising waters in mineral vein formation.

We cannot avoid the conclusion that colloids or 'gels' may be a form of matter calling for serious attention

*Inst. of Min. and Met., April 18, 1912.

in our studies of the formation of minerals, whether in the vadose or the deep-seated zones.

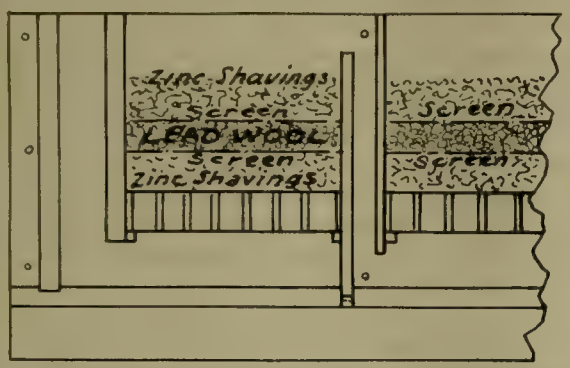
December 17, 1914. J. F. Kemp.

[The influence of colloids in ore formation is just beginning to be appreciated, though the fact that silica enters solution as a colloid and travels as such is old.—Editor.]

Lead Wool in Cyanidation

The Editor:

Sir—A number of years ago, while in New York City, I had my attention attracted to the lead-wool used in calking gas mains, and at once thought of using it in conjunction with zinc as a precipitating agent in the cyanide process. Accordingly, I took some ten pounds of it with me to Nicaragua and used the lead wool as an intermediate stratum in the head compartment of one of our zinc-boxes. The fibres, being just like the zinc shaving but less elastic, lend themselves easily to the process. As the precipitate, for the month I used this lead-wool zinc-shaving couple, was decidedly the higher grade (36.1% bullion against a 25% bullion precipitate), I thought it might interest some one else to give this material a more thorough test than I could give it. I realize there is nothing new in the use of lead or its salts, but I have never seen this lead-wool, which is analogous to zinc shavings, used, and I wish to offer this as a suggestion for some one who has the opportunity to make a conclusive test.



SECTION SHOWING METHOD OF PLACING SHAVINGS.

New York, December 12, 1914. Arthur Feust.

Lake Superior Copper Mining

The Editor:

Sir—In the article appearing in your issue of December 5, by Thomas T. Read, he speaks of "large masses of copper, one of which weighed 130 tons." In my weekly copper letter published recently I referred to one mass of copper which will represent a total weight of thousands of tons, before it is exhausted. This mass was found at the Trimountain mine, one of the Copper Range Consolidated group. It has been producing chunks, weighing from one ton to one and a half tons, for over a year, and men are still cutting from the same mass, and likely will be for some time to come. This mass was found 50 ft. above the 25th level and has run continuously, without a break down to the 27th level, a distance of nearly 300 ft. to date. It appears just as persistent now as ever. It averages a width of 40 ft. and is about 6 or 8 in. thick. Technically there might be some idea that this is a fissure and not a mass, but I believe the best authorities are agreed that it is in reality a mass, as it appears in the foot-wall and did not pinch out at any point. Two miners work on it all the time, using a chisel propelled by air. Its richness is such that wages are paid out of the chips cut off by the chisel. Both Calumet & Hecla and Ahmeek developed somewhat similar formations. For eight levels, 800 ft. on the angle, No. 11 shaft of the Calumet cut through this solid slab of copper. It occurred in the hanging, however, and was not continuous. Ahmeek's fissure picked up solid slab copper at the surface and carried it to the sixteenth level.

Homer A. Guck.

Houghton, December 10, 1914.

Shoveling Machines at Flat River

The Editor:

Sir—I have noted the article on our shoveling machines at Flat River, by E. H. Leslie, which appeared in your issue of November 21 and am interested in the data given regarding the performance of these machines at the Federal Lead Co. and the St. Louis Smelting & Refining Co.'s properties.

The statement regarding repair costs on the machine at the St. Louis Smelting & Refining Co.'s plant is erroneous and does an injustice to the machine. The only repairs necessary on this machine while in use at that plant were the renewal of one axle and two cast iron truck wheels, and repairs on a motor armature, which had been injured by exceedingly low voltage. The cost of these repairs could not possibly have been over $75, and the other charges mentioned in the lump sum of $322.48 include the cost of putting the machine under ground, erecting it, arranging the tracks and power wires, and later removing the machine. They are not properly chargeable to repairs.

William Whaley.

Knoxville, Tennessee, December 2, 1914.

[We are, of course, glad to publish Mr. Whaley's criticism of the figures presented in Mr. Leslie's article. As stated in that article "The repair charges of 0.033c. per ton at the St. Louis Smelting & Refining Co.'s property will appear high, but it must be said that the loader was operating at a shaft three-fourths of a mile from the machine shop and was charged with the time of the men going and coming as well as when actually working on the machine. The loader was new at the time of the test and it was thought best not to have the operating men look after the repair work." The repair cost as published is that supplied from the Company's record of the performance of the machine.—Editor.]

CONCENTRATES

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

TUNGSTEN is principally used in the manufacture of high-grade tool steel and for filaments in electric incandescent lamps.

A PLANT using a flotation process, to treat 600 tons of ore per week, is to be erected at the Mt. Lyell copper mine, Tasmania. This will deal with ore from the Lyell Comstock mine for the present.

SILVER CONTAINED in the 135,853,409 lb. of copper recovered from Michigan mines in 1913 amounted to 295,173 oz. This was equal to 0.04 oz. per ton of 'rock' treated, 7,016,370 tons being stamped.

IRON to the amount of 0.023% was found in analyses of tomatoes grown in Florida. The soil in which they were grown contained 1.06 to 1.3% iron. The acidity in this vegetable is supposed to be due to citric acid, according to C. A. Brautlecht and G. Crawford, in the *Journal* of the American Chemical Society.

FIREPROOF is a term loosely used in building construction, and conveys a false sense of security, because at present nothing now known is strictly fireproof, but may be as 'fire resistant' as modern ingenuity and materials can make it. Gypsum is now used as a fire-resistant or for steel protection on account of its low conductivity of heat, low amount of expansion, incombustibility, lightness, strength, adaptability, water effect, and small corrosive effect.

GOLD AND SILVER extracted by processes in the United States in 1913 was as follows, according to the U. S. Geological Survey:

Process.	Gold, %.	Silver, %.
Placer mining	24.9	0.2
Amalgamation	21.5	0.6
Cyanidation	31.2	19.7
Chlorination	0.3	....
Smelting	22.1	79.5
Total	100.0	100.0

POWER HOUSE for the Mt. Margaret hydro-electric scheme of the Mt. Lyell company is 110 ft. long, 72 ft. wide, and 30 ft. high, of concrete. It contains four turbines of 1750-hp. each, driving four 1200-kw. generators; three turbine-driven exciters of 50 kw. each; a 10-ton traveling crane; and a complete controlling and distributing apparatus mounted on a switchboard of white marble. The two transmission lines are five miles long. The sub-station is of concrete, and 73 ft. long, 66 ft. wide, and 27 ft. high. Rainfall at the power-site was 94 in. during the six months ended September 30, 1914. The blower building for the blast-furnaces and converters is of steel, and 100 ft. long, 45 ft. wide, and 27 ft. high. Four electrically driven turbo-blowers, each of 25,000-cu. ft. capacity, and two of 3500-cu. ft. capacity, were installed in that time. Power was delivered at the end of November. This electric plant is valued at $600,000.

A STUDY of the copper deposits of Ely, Nevada, by Alfred R. Whitman, resulted in the following conclusions: (1) that the matrix of the ores is an altered monzonite-porphyry, and that this rock is the oldest of the local monzonitic rocks which have intruded the Devonian and Carboniferous sediments, as a series of stocks; (2) that the chief agency in producing the present state of alteration of this rock was descending meteoric water, and that the present ores are due essentially to a diffused secondary deposition of chalcocite by this process; (3) that this enrichment occurred above the groundwater level; and (4) that it had occurred before the eruption of the rhyolite.

BAR GOLD IMPORTED BY ENGLAND per year amounts to as much as £47,000,000 in normal times. Owing to war risks, the metal has been held in Australia, Africa, Canada, India, New Zealand, and other colonies, and the Bank of England has made advances on deposits. In this connection the following official notification has been made regarding Australia: "The government of the Commonwealth of Australia having agreed to receive, on behalf of the Bank of England, deposits of gold, the bank is prepared to purchase, on the basis of $18.66 per ounce, such bullion as may be deposited to its order in the name of the Commonwealth treasurer. The gold is to be deposited with the federal treasury at Melbourne, and with the Commonwealth Bank at the capital cities other than Melbourne. The Bank of England is also prepared to purchase sovereigns ($4.80) of legal tender weight deposited as above in the name of the Commonwealth treasurer." An advance of a sum representing 97% of the value of the gold and of the sovereigns is to be paid on account, and the balance adjusted on delivery in London, after deducting the expenses of shipment, etc., to England. The use of the word 'purchase' in regard to sovereigns suggests an unusual method of dealing with coin legally current throughout the British Empire. As, however, it is intended that coins of legal current weight thus deposited, should change hands on the basis of their face value, the arrangement merely affords facilities for placing sovereigns to the credit of the Bank of England in Australia, subject to reimbursement of the expense attaching to transit 'home.'

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

JOPLIN, MISSOURI

REVIEW OF THE PAST YEAR, AND PROBABLE MARKET IN 1915.—ORE SHIPMENTS AND VALUES.

The value of zinc and lead ores shipped from the 20 districts of Missouri-Kansas-Oklahoma in 1914 totaled $11,627,327, compared with $14,356,461 in 1913, and $18,043,379 in 1912, which was the banner year.

The accompanying table shows the shipments of zinc and lead ores from the district for the past year:

	Zinc-blende.		Calamine.		Lead.		
	Pounds.	Value.	Pounds.	Value.	Pounds.	Value.	Total value.
Webb City-Carterville, Missouri	136,103,130	$2,666,181	.....	.....	34,951,660	$824,944	$3,491,125
Joplin, Missouri	90,157,650	1,942,869	5,213,340	$50,984	13,707,891	316,187	2,310,040
Miami, Oklahoma	56,969,070	989,268	.....	.....	17,033,465	392,749	1,382,017
Duenweg, Missouri	42,255,830	848,201	315,580	3,482	5,930,572	136,605	988,288
Alba-Neck City-Purcell, Missouri	49,044,580	854,109	459,880	5,390	613,450	13,502	873,001
Galena, Kansas	32,182,760	600,361	.....	.....	3,924,768	86,482	686,843
Oronogo, Missouri	18,729,050	379,700	.....	.....	3,255,320	76,751	456,451
Granby, Missouri	9,128,410	155,811	20,863,660	233,945	843,690	18,077	406,833
Lawton, Kansas	13,498,978	264,626	.....	.....	201,810	4,373	268,999
Spring City-Saginaw-Spurgeon, Mo	6,245,940	116,024	3,614,470	38,864	1,606,510	35,809	190,697
Belville-Klondike, Missouri	8,985,820	175,901	.....	.....	337,200	5,561	181,462
Carl Junction, Missouri	7,194,920	142,992	.....	.....	46,090	1,055	144,047
Carthage, Missouri	3,724,940	69,270	.....	.....	40,210	920	70,190
Cave Springs, Missouri	2,796,755	54,950	.....	.....	31,450	685	55,635
Aurora, Missouri	1,000,200	17,332	1,905,160	19,766	460,440	10,823	47,921
Sarcoxie, Missouri	1,704,990	35,990	.....	.....	.....	.....	35,990
Springfield, Missouri	677,000	15,462	96,920	1,056	.....	.....	16,518
Wentworth, Missouri	728,260	13,608	93,290	616	.....	.....	14,224
Quapaw, Oklahoma	381,430	5,815	.....	.....	.....	.....	5,815
Seneca, Missouri	23,630	231	.....	.....	.....	.....	231
Total shipments	481,533,343	$9,348,701	32,562,300	$354,103	82,984,526	$1,924,523	$11,627,327
Average value per ton	.....	38.82	.....	21.13	.....	46.38	.....
PRODUCTION BY STATES							
Missouri	378,501,105	$7,488,631	32,562,300	$354,103	61,824,483	$1,440,919	$9,283,653
Oklahoma	57,350,500	995,083	.....	.....	17,033,465	392,749	1,387,832
Kansas	45,681,738	864,987	.....	.....	4,126,578	90,855	955,842
Total	481,533,343	$9,348,701	32,562,300	$354,103	82,984,526	$1,924,523	$11,627,327

While 1914 was a year of comparative inactivity, the outlook for a heavier production and higher prices in 1915 is unusually bright. The factor of greatest importance is the added demand for spelter resulting from the European war. Exports within the past few months have been more than 65 times heavier than they would be under normal conditions. The heavy demand for export continues, and it is doubtful if the combined production of all the United States smelters can meet this demand, and at the same time supply the ever growing domestic demand, which is now much better in view of the recent eastern railroad rate decision, which will mean increased steel orders, these, in turn, creating a stronger market for zinc.

While shipments from the districts in the aggregate are

TYPICAL MINING SCENE IN THE JOPLIN DISTRICT, BETWEEN WEBB CITY AND ORONOGO.

lighter than in the past few years, a number show important gains. Among those to show the greatest development are Miami, Oklahoma, Alba-Neck City, Missouri, and Lawton, Kansas.

The new year dawns with ore prices at a much better figure than they were a year ago, the present offerings being $50 to $52, basis of 60% metallic zinc, or about $10 better than at this time in 1914. This is from $5 to $6 higher than they were at the beginning of 1912, while the outlook is such that there is every reason to presume that strong prices will continue throughout the year.

NEW YORK

American Interest in Mines in the Fighting Zone.—Copper and Rubber Notes.—German Potash.

There has been considerable interest here in the raid made on the properties of the Caucasus Copper Co. by Turkish troops last month, not only because J. P. Morgan & Co. has a considerable interest in the property, but also because R. T. White, formerly manager at the Braden and Balaklala mines, was wounded by the troops while he and his staff were engaged in attempting to defend the property. The mine is only a few miles from the Turkish frontier in the Mourgoul valley, 40 miles from Batum. The Russian government is reported to be taking prompt action toward regaining control of the district, but the latest advices are that it is still in possession of the Turks, and both the mine buildings and the town occupied by the employees are reported to have been burned. The many friends of Mr. White have made strong efforts to learn his whereabouts and the extent of his injuries; a cablegram received recently states that he has made his way safely to Tiflis, and has already almost completely recovered from his wound.

The spirited note sent by the State Department to the British government in regard to the seizure and detention of American ships carrying cargoes destined to neutral countries has been the chief theme of interest during the week. The position taken by our State Department is so sound and even moderate, in view of the circumstances, that no offense could legitimately be taken by Great Britain. On the other hand, it is somewhat doubtful whether that country will take any effective action, and it is quite probable that, as in earlier protests, there will be a long delay before any reply is made at all, and then finally a statement will be made which is generally reassuring, but does not improve the situation as a matter of fact in any way. Other interests than the copper producers are affected by the policy which Great Britain has been pursuing, and the rubber manufacturers are reported to be in a bad position. The larger part of the rubber production of the world is grown in British colonies, and the rubber is sent to London to be sold at auction, being shipped thence to the United States. Great Britain has put an embargo on the export of raw rubber, and all the material is accumulating on the London docks, while the manufacturers here cannot get any except by buying direct from Brazil. The Brazilian producers quite naturally take advantage of the situation to charge all they can get. If the rubber manufacturers could be assured that the situation would remain as it is now, they would be likely to go ahead and pay higher prices for their raw material, passing the increased cost along to the consumer, but it is quite possible, of course, that England may raise the embargo at any time and thus turn a flood of cheap rubber loose on the market, thus ruining the men who stocked up at the high prices.

Returning to the subject of copper, it is interesting to notice that since the note was sent to Great Britain another shipment of copper has been seized, and it is reported that altogether something like 45,000,000 lb. of metal has been detained in this way. This is alone enough to unsettle the copper market, as there is no knowing when the question of the disposal of this metal will be settled, nor what will be done with it. Exports from this country during August, September, October, and November of this year averaged about 50,000,000 lb., compared with 75,000,000 lb. average for the same months last year. The export figures look fairly good, considering the disturbed conditions, but when it is remembered that nearly one-quarter of the copper shipped in those four months is being held and will possibly be seized, the situation is not nearly so favorable as might be supposed.

The German Kali Syndicate has at last arranged to repay to potash consumers in this country the $1,000,000 refund which was authorized last June by the Reichstag, being the amount paid by the Americans under protest during 1910 and 1911 during the operation of the German potash law which was enacted to do away with all the favorable American contracts. The payment is not to be made in money, but in potash salts, which are to be shipped at a valuation of $4 per ton higher than the former contract prices, on the basis that the extra cost of shipping at this time justifies the advance. Since the Syndicate has notified the trade that it is obliged by the war to rescind its regular contracts, it is somewhat puzzling that it is able to arrange to pay its indebtedness in potash salts. The situation is not likely to cause American consumers to feel especially grateful to the Syndicate, and the California producers when they get into stride should reap the benefit of this natural irritation.

WASHINGTON, D. C.

Bill to Separate Railroad and Producing Corporations.

A bill deemed of importance is one introduced in the House of Representatives by Congressman Adamson, chairman of the Committee on Interstate Commerce, and prepared by the Attorney General. It seeks to divorce railroads from producing corporations. Mining is included in the purview of the bill. This bill proposes that from January 1, 1917, it shall be unlawful for any railroad to transport in commerce any articles or commodities thereafter manufactured, mined, or produced by such railroad company, or under its authority directly or indirectly, or by any person, firm, or corporation subject to its control in any way, the prohibition applying irrespective of whether there is any relation, direct or indirect, between the railroad company and the producer of any article or commodity at the time of transportation. Lands for the foregoing purposes cannot be owned or controlled in any way. Violations will be deemed a misdemeanor and be punishable by fines or imprisonment.

BOSTON

Boston's Interests in Cotton and Copper.—Boston Finances.—Burton and Lawson.—Quincy A. Shaw and Albert H. Holden.—Calumet & Corbin.

The International diplomatic duels over cotton and copper as contraband of war have been of vital concern to Boston, fully as much so as to the South where cotton is grown, or to the West where copper is recovered. Boston stock market and textile interests have been watching the administration closely, and hoping that a way out would be found without affecting our neutral attitude.

There have been comparatively few changes in the banking and stock brokerage alignment beginning with the new year in Boston. Boston houses have weathered the storm caused by the war abroad as well as any in the country, and are ready for greatly improved business in 1915.

Richard J. Burton, a former confidential secretary of Thomas W. Lawson, and a few years ago a member of the Curb, who made some sensational markets for Champion Copper, Humboldt Smelter Mines, and Southwestern Development Co., has

[illegible] as it were and is again actively manipulating [illegible] and Humboldt, on the Curb. The Humboldt is an Arizona corporation which was organized to take over and operate about 80 acres of mining ground near the Humboldt smelter at Big Bug, Arizona. Capitalization is 150,000 shares, par value $5. Champion Copper is being reorganized and assessed the authorized capitalized stock of 2,000,000 shares being reduced in par value from $1 to 10c. Champion is called the Copper Baby of the Curb. The Company has about 20 acres of ground at Copper Hill, Taos county, New Mexico. Burton uses Lawson methods of advertising and manipulation in handling these stocks. Thomas W. Lawson is apparently inactive in a market way. He came East from Oregon, just before the election, to vote for his relative by marriage Samuel W. McCall, and to settle some litigation, and immediately went back West.

The Utah Metals & Tunnel Co., a reorganization of the Utah Metals Co., is going back on the Boston Curb, and it is stated that the strong interests behind the issue will make a broad market for it. The old Company had a capitalization of $7,500,000, which has been reduced to $500,000. The old Utah Metals stock never made a good showing on the Curb, selling at its highest price the first day it appeared for trading, around $2.50 per share. From this eminence it descended to less than 10c., and a reorganization became necessary. The new Company is a Maine corporation, and through assessments has accumulated over $100,000 cash in the treasury for development purposes. The Company is a consolidation of several mining companies and several tunnels in Bingham, Utah, and is known locally as the 'Big Tunnel.' The Company owns the larger part of West mountain, at the head of Bingham cañon, separating it from Middle cañon, at the foot of which is the town of Tooele, the site of the International smelter. The Company owns about 3400 acres, half of which is available for development, with 600 acres of proved mineralized ground. It has a tunnel completed from Bingham to Tooele, a distance of over two miles. Mining, transportation, and supplying water are the three principal sources of income. The Clark and Coolidge interests and D. C. Jackling are prominently identified with the present Company. The stock, $1 par, has been selling, prior to listing, up to $1.25 per share, and higher prices are predicted for it.

Quincy A. Shaw, president of the Calumet & Hecla Mining Co., has been for some time past suffering from mental breakdown, and grave fears are expressed as to his recovery. His deplorable condition is said to be directly traceable to brooding over the protracted and bitter fight in the Lake district with the Western Federation of Miners, in which the miners were defeated. The Shaw interests are among the largest taxpayers in Boston, and he has one of the largest among the famous estates at Pride's Crossing, Massachusetts, a few miles out of Boston. His neighbors are Henry C. Frick, W. H. Moore of Wall Street, John Hays Hammond, and other magnates.

The late Albert F. Holden, mining engineer and financier, connected with Alaska Gold and several Boston mining enterprises, made provision for the disposition of a large part of his estate in establishing in Lakeview cemetery, at Cleveland, Ohio, his home, near the Forest Hill estate of John D. Rockefeller, a mortuary *arboretum*, a sort of Westminster Abbey, as a place of honor for the burial of the illustrious dead. Mr. Holden, some time before his death, enjoined his executors against throwing his mining stock holdings upon the market in settling his estate, with the result that there has been no disturbance in the market values of these stocks due to liquidation of his interests.

One of the active Curb stocks recently has been Calumet & Corbin, a Company which has had many disappointments in developing a paying proposition. Calumet & Corbin, after having failed in making a mine in the Corbin district, Montana, has acquired a group of 15 quartz lode-mining claims and two millsites, known as the New Era in the Freeland district near Idaho Springs, Colorado. These mines were located in 1876, and have been worked almost continuously ever since. It is said that when the Calumet & Corbin company acquired the property a year ago the records showed $90,000 net earnings in two years. The former president of the Company is James Wilcox, an old Cornish miner who resigned his position as superintendent of the Mass Consolidated Mining Co., in the Lake district, in order to give his attention to the development of the Company's properties at Corbin, Montana, without result. The Calumet & Corbin stockholders entered into an agreement with C. A. O'Leary, of Minneapolis, who agreed to secure for them a property and finance its efforts to make good. Mr. O'Leary has been in Boston recently in connection with the making of a market for this issue, which has been selling so far as from 5 to 20 cents.

TORONTO, ONTARIO

NIPISSING AND MCKINLEY.—DARRAGH OPTIONS.—PETERSON LAKE SURPLUS.—PEBBLE SUPPLY.—WAGES DISPUTE.—DOMINION COAL COMPANY.

The Nipissing company has taken up its option on the Teck-Hughes property in the Kirkland Lake district, although recent developments hardly proved as encouraging as was anticipated. No. 3 vein on the 185-ft. level, though it produced some rich ore, proved considerably shorter than the shoot at 75 ft.——The McKinley-Darragh of Cobalt has given up its option on the Jupiter mine, the stock of which received quite an impetus for a while on account of the general impression that the deal would go through. It is understood that the McKinley-Darragh interests made a new proposal which was not entertained by the Jupiter directors.——The quarterly statement of the Peterson Lake company shows a surplus of $208,471 on hand. During the quarter, 967 ft. of driving and cross-cutting, and 255 ft. of rising was done.

The board of conciliation appointed by the labor department at Ottawa, to investigate a dispute over wages between the owners of the Miller Lake-O'Brien mine, Gowganda, and their employees, reports that all danger of a strike has been averted.

The supply of pebbles for the Cobalt and Porcupine mills from France and Denmark having been cut off by the war, a shortage was feared, but this has been averted by the arrival of a large consignment from Newfoundland.

The Dominion Coal Co. of Sydney, Nova Scotia, has had a poor year on account of the war, although the Canadian market has considerably improved. The total coal shipments of the Company by the St. Lawrence route totaled 1,921,491 tons, compared with 1,698,131 tons last year, and would have been still larger had trade conditions been favorable. The approximate output from the Company's mines in Cape Breton will amount to about 4,300,000 tons, against 4,740,000 tons in 1913. The Springhill collieries, a sudsidiary, will produce approximately 430,000 tons, compared with 381,000 tons last year, so that the net decrease in the combined outputs will be about 390,000 tons. The Company is finding it practically impossible to compete with American operators for a share in the South American trade, in view of the advantage enjoyed by the latter in freight rates with the aid of the Panama canal, and the markets which might under ordinary conditions be found in Norway and Sweden are closed by the war. The starting of an additional blast-furnace by the Dominion Steel Co. will relieve the coal company of a considerable part of the surplus slack which has accumulated, and work is likely to be steadier during 1915.

THE MINING SUMMARY

The news of the week as told by our special correspondents and reflected by the local press.

ALASKA

JUNEAU

November returns of the mines on Douglas island were as follows:

Details of work.	Mexican.	Treadwell.	United.
Stamps working	120	540	240
Ore crushed, tons	17,850	69,699	38,514
Concentrate saved, tons	397	1,591	849
Gold recovered	$39,199	$129,450	$82,681
Profit	4,614	18,091	6,070

CONCENTRATING MILL, BEATSON COPPER CO., LA TOUCHE, ALASKA.

Construction expenditure was $8601, $35,629, and $21,192, respectively.

ARIZONA

A nominal output of quicksilver has been reported to the U. S. Geological Survey from both Maricopa and Yuma counties in 1913 and 1914, in the Mazatzal range and in the Quartzsite district, respectively. The production from both localities greatly decreased in 1914.

COCHISE COUNTY

Damage by floods to the town of Bisbee is estimated at from $10,000 to $15,000.

YAVAPAI COUNTY

The Western Gold & Copper Co. has been incorporated to operate its mine at Providence, the post-office being at Huron, with W. W. Lewis as superintendent. During the past few weeks the Company has spent about $2000 in sampling and examining the Great Belcher and nine other claims. The assays gave an average of $6.75 per ton for the large deposit, which so far is 54 ft. wide. In the four principal claims over 5000 ft. of work has been done, including two 500-ft. adits, a 700-ft. shaft, and other connections. It has been decided to mine the deposit by open-cut methods, which will make a low mining cost. A 150-ton plant consisting of crushers, rolls, amalgamating plates, concentrators, and a flotation process will be erected in the near future to treat the gold-silver-copper ores. F. W. McConnell and G. Demaine are associated with the Company as mining engineers and assayer, respectively.

A plant using the Wagner process is under construction at some mines near Crown King, by the Grey Eagle Reduction Co. This electric process is to treat gold-silver-lead-zinc ores of the Wildflower and other properties near by.——The 'Hog-Back' at Jerome has been sold to F. S. Stephens, of Scotland, for $25,000. A good tonnage of 5 to 40% copper ore is said to exist.

CALIFORNIA

CALAVERAS COUNTY

Suits for damages for alleged injury to cattle and vegetation, etc., by smelter fume have been begun in the United States District Court of San Francisco against the Penn Mining Co., which has a smelter at Campo Seco, by Leroy Southworth, who asks for $17,511, and J. G. and F. W. Foster for $20,884.

INYO COUNTY

The new hoist, mill, and cyanide plant of the Wilshire Bishop Creek company is ready for work, but on account of the winter the mine will not be unwatered till February, and the plant in April. E. W. Walter is superintendent.

NEVADA COUNTY

(Special Correspondence.)—San Francisco people are examining the Orleans mine, and a few men are examining oreshoots in an old rise. The property was formerly operated by the Sultana Mines Co., and for years was a large producer. ——Driving on the vein recently cut near the 900-ft. level of the Union Hill mine is under way. The shoot is about two feet wide, with some free gold visible.——George W. Root and associates are planning an early resumption of operations at the Kenosha, about four miles below town. It is understood the Kenosha Mining Co. will be reorganized, the shaft deepened, and extensive lateral development carried forward.——A small force is working at the Gold Mound, from which some ore was recently crushed at the Golden Center mill with satisfactory results.——Ore ranging from $15 to $50 per ton is being mined at the Colling property, near Rough and Ready. There are three small veins crossing the main orebody, the latter assaying $9 per ton.——Recent work in the Champion mines, in the Nevada City district, has been highly satisfactory.——The Phoenix mine has been taken under bond by J. A. Largent, and arrangements are being made for extensive work. Formerly known as the Sneath & Clay, the property produced much rich ore, but has been idle several years. It is equipped with an excellent hoisting and pumping plant, also a 10-stamp mill.——A good deal of new work is going on in the Oustomah, now operated by the owners. Mill ore has been opened at several points in new territory. Frank Morgan is superintendent.

Grass Valley, January 2.

The new 20 stamps at the Empire mine are now working. They weigh 1370 lb. each, and in place of amalgamating plates a new device of Frank Hooper is used, giving good results. ——Owing to San Francisco capital being interested, the Deadman's Flat district is showing greater activity.——Work at the Golden Center of Grass Valley is giving good results.

PLACER COUNTY

During 1913 there were 253 proofs of assessment work done on gold mines filed for record. It is expected that 1914 will show a total expenditure of about $30,000, an increase over the previous year.——It is alleged that the Yukon Gold Co.'s dredge on the American river, near Auburn, has been polluting the water supply of Fairoaks and Orangevale, and an injunction suit to prevent operation of the boat was started. The Company does not admit the charge, but will help remedy the trouble by assisting to construct a settling basin in the North

Fork supply ditch. The cost is estimated at $5000, of which the Company will contribute $2500, and the El Dorado Dredging Co $1000, on certain agreed terms. The Yukon company asserts that it is unfairly attacked, as the Mountain Quarries Co. and Pacific Gas & Electric Co. deposit debris in the river.

SHASTA COUNTY

Owners of the Shasta Belmont near Heroult will resume work early in February. The mine was closed on account of the copper market. The ore contains copper, gold, and silver.

SIERRA COUNTY

The Alleghany district shows encouragement for the coming year. There has been plenty of employment for miners. Deep mining is to be a feature. The Rainbow mine is being worked under lease. Quartz and gravel mining is being carried on in the same adit of the North Fork mine, near Forest, by two companies. Both are doing well. The Tightner continues to produce rich ore, while prospects at the Plumbago, Eldorado, Twenty-one, Sixteen-to-One, and others are good.

TUOLUMNE COUNTY

A drainage adit over 5000 ft. long has been driven into Table mountain near Columbia, and in February miners will start to extract the gravel which before could not be reached on account of the water. According to A. L. Horner, general manager, a great deal of gold will be recovered and several hundred men employed.

YUBA COUNTY

The Guggenheim interests have made a final settlement on several claims acquired on the Yuba river. Marysville people were interested in the deal.

COLORADO

GILPIN COUNTY

Owing to the Frontenac and Aduddell mines, in Russell gulch, being closed, the output of this county in 1914 will show a considerable decrease. These were large producers. A number of other properties which are idle contain profitable ore. Efforts are being made to open some of them on Quartz hill, where are the Kansas, Burroughs, and Gunnell veins. The latter is worked through the Newhouse tunnel, ore being treated at the Argo mill.——The Lake mine, owned by H. Sayre, is one of the best producers at present. It is operated at 1700 ft. through the Big Five tunnel, ore going through to Idaho Springs. The November output was about $30,000.——*The Weekly Register-Call* estimates the year's production of the county at about $1,000,000.

LAKE COUNTY (LEADVILLE)

The weather at Leadville has been cold, and on one day last week the temperature was 1° above zero. On December 27 the maximum was 38° and minimum 4° above zero. There has been fear of a shortage of water for the mines. The Iron Mine ditch, which is very low at present, supplies many properties. There has not been much snow to augment the supply. The Wolftone has connected a pump with the Carbonate Hill reservoir of the Leadville Water Co., and others will have to do likewise.

TELLER COUNTY (CRIPPLE CREEK)

Cripple Creek mines produced $1,165,855 from 81,250 tons of ore in December. The smelters received 5000 tons of $55 ore, while the local plants treated material assaying from $2.10 to $7 per ton. Dividends paid in 1914 were as follows:

Golden Cycle	$1,005,000
Portland Gold	360,000
Vindicator Consolidated	270,000
Elkton Consolidated	200,000
Stratton's Independence	100,000
Mary McKinney	78,567
El Paso Consolidated	50,000
Stratton's Cripple Creek Mining & Development Co (Stratton estate)	40,004
New Haven	17,617
Jerry Johnson	12,500
Gold King	10,000
Cresson Consolidated (estimated)	500,000
Strong (estimated)	250,000
Total	$2,893,684
Profits of leasing companies and lessees (estimated)	250,000
Total	$3,143,684

GEORGIA

CARROLL COUNTY

(Special Correspondence.)—A 50-ton cyanide plant is being erected here by T. H. Aldick. The orebody to be treated is of considerable size, being a low-grade quartz, and when blasted 85% crumbles to about 8 mesh and finer. No mill is necessary, and the product cyanides readily, the gold being very fine. Walter F. Posley is superintendent.

Villa Rica, December 25.

IDAHO

SHOSHONE COUNTY (COEUR D'ALENE)

In reviewing the mining outlook of the district, *The Wallace Miner* states that while 1914 produced no records, it was significant of work done which will have a bearing on the future. The most important achievements were the new processes for recovering more metal in the copper, lead, and zinc ores, mainly flotation systems. Also the process being tried by the Bunker Hill & Sullivan company to do away with smelting the mill products. There were numerous important mine developments, and ore reserves show increases. Dull times have not been felt so much in the Coeur d'Alene as in other parts of the country.

The predicted probable fight between the Washington Water Power Co. and the Montana Power Co. has started. The former has filed a complaint against the Montana Power Co., the Thompson Falls Power Co., the Federal Mining & Smelting Co., and the Tamarack & Custer Consolidated Mining Co., alleging conspiracy. The Washington company asks a restraining order forbidding the defendant companies to erect transmission lines and selling power, claiming that the two power companies have not filed articles of incorporation in Idaho nor appointed resident agents. Some interesting points will be raised in the suit. Meanwhile the Montana company's lines are being extended to the mines.

The Bunker Hill & Sullivan company paid dividend No. 208 on January 4, amounting to $81,750. The total to date is $15,792,000.——Two 6 by 14-ft. Chalmers & Williams patented adjustable quick discharge tube-mills are being installed in the Hunter mill, and not the Hardinge type as published in the *Press* of December 26. A 5 by 14-ft. C. & W. mill had been previously at work in this plant.

MONTANA

SILVERBOW COUNTY

Excepting development, mining has been suspended in the Original mine of the Anaconda company, and work will be resumed in the Badger State mine, which was closed in August. The 1000 tons daily cut off from the former will be made up by a similar quantity from the latter.

NEVADA

CHURCHILL COUNTY

The Nevada Hills mine produced 6313 tons of $6.21 ore in November, of which 44.4c. per ton, or $2797, was profit. Assets

amount to $257,937, including silver worth $28,739, less $6429 overdraft at the bank. The annual report will be distributed early in February.

ESMERALDA COUNTY

The Goldfield Consolidated Mines Co. has closed its New York transfer agency. Any future transfers of shares will be made at the office at Goldfield. On February 27 the twenty-first dividend, of 15c. per share, will be distributed.——The fourth rise above 1017 ft. in the Jumbo Extension has cut $28 to $104 ore at a height of 40 ft. It contains gold, silver, and copper.——There is now 9 ft. of ore in a rise above 1750 ft. in the Atlanta. Three feet of this assays $60 per ton, but the general average is $23 per ton.

According to A. A. Codd, the line from Nenzel to the Rochester Mines Co.'s mill, a distance of 11 miles, is finished, and is carrying material to Rochester. The new mill should be ready by February 15. The ore-shoot in the Codd lease is 8 ft. wide, assaying $20 per ton. Ore reserves are 12,000 tons on the dump, 2000 tons in stopes, and 40,000 tons blocked out in the old vein.——The Big Four is shipping up to 40 tons of $25 to $35 ore daily.——The Rochester district's output is 150 tons per day.——The two-stamp mill of the Forvilly-Rochester Mines Co. has produced $18,000 to date.——The Seven Troughs Coalition mine produced the largest amount of gold in its history in December. The last bar was worth $7000.——The U. S. Geological Survey estimates the silver output of Rochester in 1913 as 701,407 ounces.

LINCOLN COUNTY

At the Amalgamated Pioche the No. 1 shaft of the Raymond and Ely mine has been sunk to 1400 ft., and 800 ft. of cross-cutting has been done. The orebody there is as strong as at 1200 ft. Stoping is under way between these levels, the zinc ore assaying 40% zinc, $2.50 gold, 30 oz. silver, and 2.5% lead. Shoots of rich lead-silver ore are also found. According to Trippe & Co., of New York, a mill is to be erected to treat the ores.

LYON COUNTY

At the Nevada-Douglas mill, concrete and framework of the ore-bins is complete. Excavating for the crushers is done. Work on the digester is well on, also on the absorption towers. Generally good progress is being made, although the weather has been cold.

NYE COUNTY

The U. S. Geological Survey estimates the output of the Tonopah district in 1914 as 577,000 tons, yielding 11,757,000 oz. silver, against 11,563,437 in 1913. The gold output was $2,660,000 and $2,613,843 respectively. The output of the district in the last week of 1914 was 8950 tons, worth $187,060.——The report of the Belmont for the quarter ended November 30, 1914, shows that the revenue was $728,170; net income, $372,020; and due from smelters, silver stored, loans, and cash was $1,333,637.——Some encouraging developments were made in the Montana last week.——The Extension company's new 150-hp. Nordberg hoist is ready for work. A Rockwell duplex melting furnace is being erected.——Shareholders in the Mizpah Extension have ratified the lease and option to the Tonopah Mining Company.

The three main operating companies now at work in the Manhattan district are the Big Pine, White Caps, and Consolidated. The White Caps works the 10-stamp mill and cyanide plant recently operated by Mushett and Wittenberg on Big Pine ores, and treats about 50 tons per day. The mill work is under the supervision of J. P. Montague, some time at Tonopah. The mine is developing well.——About 250 tons of ore is mined daily from the Big Pine, of which 125 tons goes to the tube-mill.——The Manhattan Consolidated is to sink its shaft deeper. The Associated mill is making a good recovery.——The U. S. Geological Survey estimates the yield of Manhattan in 1914 to be 40% less than in 1913.

WHITE PINE COUNTY

The Cumberland and Mulligan claims at Osceola are the subject of a lawsuit between F. D. Goody and J. H. Marriott. The latter owns twelve-fifteenths and Mr. Goody, it is claimed, has been interfering with him, and may stop a deal with Denver people. An injunction has been granted, it is claimed.

NEW MEXICO

The passage of a more liberal mining law, and of a law to encourage the oil industry in New Mexico, are the most important recommendations made by state land commissioner R. P. Ervien. He hopes to see both recommendations carried out by the legislature that convenes January 12. The present mining law, he declares, is too stringent, particularly in relation to prospecting.

GRANT COUNTY

In the suit of Mary Belle Whitehill v. the Chino Copper Co. and another for $20,000 damages in connection with an accident in a street of Hurley, the plaintiff was awarded $8800.

LINCOLN COUNTY

The Alto Light & Power Co., capital $150,000, has been incorporated at Santa Fe to supply electric power to mining properties in this county. The new concern is an auxiliary of the Wildcat Leasing Co., which is operating near White Oaks, in the county. Construction of transmission lines was started some time ago, and the power-plant is being enlarged for greatly increased service.

OREGON

BAKER COUNTY

Ten of twenty stamps at the Golden Gate mine near Greenhorn are ready for work. The mine is well developed.

JACKSON COUNTY

It is proposed to erect a custom mill in Grants Pass. An examination of the district mines is to be made to see how much ore is available for supply. E. H. Richard is chairman of the committee.

SOUTHWESTERN OREGON.

UTAH

The itinerary of the U. S. Bureau of Mines Rescue Car No. 2 in this state is as follows: Midvale, December 21 to 31; Salt Lake City (University of Utah), January 3 to 11; Arthur,

Jan. 12 to 13. Magna, Jan. 19 to 26. Garfield, Jan. 27 to Feb. 10. Bingham, Feb. 11 to 18. Murray, Feb. 19 to 26. Tooele, Feb. 27 to March 6, and Park City, March 7 to 18.

BEAVER COUNTY

The Moscow mine, in the Star district, shipped 11 cars of ore, worth $1600 each, in December, the same output as in November. The new shaft does away with the previous expense of haulage around the mountain. Developments at 800 ft. are good, and it is proposed to sink farther.

SALT LAKE COUNTY

The Utah Copper Co.'s mine and mill was stopped from December 27 to the end of the year. This was to give a general vacation to employees, and make necessary repairs.——In the Cardiff mine, in the south fork of the Big Cottonwood cañon, the rise is up 50 ft., showing 10 ft. of ore assaying 17.4 oz. silver and 52.3% lead. There has been 850 tons of ore shipped averaging $30 per ton.——From 12,691 tons of ore, net earnings of the Utah-Apex in November were $27,260.——Transactions on the Stock Exchange of Salt Lake City totaled 3,387,020 shares, worth $693,473, in 1914. The value in 1913 was $1,234,629.

WASHINGTON

A shipment of mineral specimens from this state has been sent to the expositions at San Francisco and San Diego. The assistant mine commissioner, Joseph Daniels, is in charge of the collection from the various mines. Spokane is to be the headquarters of the Stewart Mining Co. of Idaho, which had an office at Butte. M. W. Bacon is general manager.

The United States Assay Office at Seattle received gold valued at $8,770,058 in 1914. Of this, Alaska contributed $6,271,441; Yukon, $1,018,521; Washington, $27,907; and Oregon, $111,507. Since its establishment in 1898 it has received $227,539,656.

WYOMING

CROOK COUNTY

The Moorcroft oilfield, 12 miles north of Moorcroft on the Chicago, Burlington & Quincy railroad, is described in *Bulletin* 581-C of the U. S. Geological Survey, by V. H. Barnett. About $200,000 has been spent on development, with a return of about $1000 in oil. It has been thoroughly prospected, and the future is not encouraging.

NATRONA AND CONVERSE COUNTIES

The possibilities of oil in the Big Muddy dome of these counties is also described in the above-mentioned bulletin. The Salt Creek field was developed on a dome-shaped structure, and prospectors are busy searching for similar formations in the state with fair results. The conclusion is that if water is found at the top of the Big Muddy dome it will be useless to test further, but if dry rock or gas be found, oil may be struck lower down in the flank of the fold.

CANADA

BRITISH COLUMBIA

The Hedley company's power-plant had a trial run during the last week of 1914. It will develop 1800 hp., or twice as much as the old one, and cost about $200,000. On December 31 a quarterly dividend of 3% and a bonus of 7% was paid.

ONTARIO

The new shaft of the Casey-Cobalt mine is nearly finished, and a station will be started at 400 ft. during January. Seven drills and two stoping machines are working underground. The mill is treating 85 tons per day. There are 130 men employed in the mine and mill.

The Hollinger made a profit of $152,644 during the four weeks ended December 2, and a total of $1,630,620 for the year. There was $1,080,000 paid in dividends.

PERSONAL

R. S. BOTSFORD is now at Petrograd, Russia.

FRANK LAWRENCE has returned to Baja California.

H. S. DONNY expects to leave London for Mexico in January.

DRUMMOND MCGAVIN, who has been spending a couple of weeks in San Francisco, has returned to Toronto.

W. G. ANDERSON, manager for the Ore Chimney Mining Co., Ltd., of Ontario, is in Nova Scotia examining a mining property for that Company.

W. G. SWART is now with the Hardinge Conical Mill Co. as consulting engineer in the West, and has offices in the Foster building, Denver, Colorado.

N. C. SHERIDAN has resigned as superintendent of the Interstate-Callahan mine in Idaho, and it is stated that he will go to Mexico to engage in mining.

CHARLES W. NEWTON, of Butte, who recently resigned as superintendent of the Butte-Ballaklava, has been appointed superintendent in Mr. Sheridan's place.

A. H. BOYD is now with the C. H. Shaw Pneumatic Tool Co. of Denver, Colorado. Mr. Boyd was formerly with the Denver Rock Drill Manufacturing Company.

WALLACE N. TANNER has been promoted to the position of chief engineer of the smelter plants at Anaconda and Great Falls. For two years Mr. Tanner has been chief engineer of the Anaconda Copper Mining Co. at Butte.

Obituary

E. D. MEIER, president and chief engineer of the Heine Safety Boiler Co., died December 15. Mr. Meier was a distinguished mechanical engineer widely known in the profession. He was the founder of the Heine company, and its success and growth for many years was practically entirely due to his efforts.

THOMAS CRUSE, died, aged 78, on December 20, at Helena. He was one time owner of the famous Drumlummon mine at Marysville. Cruse was a prospector, but not the proverbial one, for he died rich. In 1886 he sold the Drumlummon for $1,000,000 cash, and a large and profitable stock interest in the property. He invested in land, livestock, and mines to good advantage, and lived a useful and honorable life. In a quiet, unassuming way he contributed largely to public benefactions and private charities.

SCHOOLS AND SOCIETIES

The SEISMOLOGICAL SOCIETY OF AMERICA bulletin for December contains a great deal of interesting matter pertaining to earth movements in various parts of the United States and the world.

The INDIANA ACADEMY OF SCIENCE held its thirtieth annual meeting at Indianapolis on December 4 and 5. There were numerous papers read on bacteriology, botany, zoölogy, chemistry, engineering, geography, geology, mathematics, meteorology, physics, and human life. These were restricted to from 5 to 25 minutes each.

The WASHINGTON STATE COLLEGE at Pullman will hold its annual winter school of mines from January 4 to March 29, and six courses will be given. Tuition is free, only a small charge being made for materials used. The school will be in charge of Francis A. Thompson, head of the department of mining engineering.

THE MARKET PLACE

Weekly Summary of Prices of Shares and Metals

Metal Prices

San Francisco, January 7.

Antimony	15 —15¾
Electrolytic copper	13½—13¾
Pig lead	4.95—5.00
Quicksilver (flask)	$51.50
Spelter	7 — 7¼
Tin	34½—36
Zinc dust, 100-kg. zinc-lined cases	9

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, January 7.—There have been good domestic and export demands for electrolytic copper, and the price advanced to 13.25c. Lead is quiet at 3.80c., and spelter strong and advancing at 5.50c. per pound.

SILVER

Below are given the average New York quotations in cents per ounce, of fine silver.

Date.		Average week ending	
Dec. 31	48.50	Dec. 2	49.33
Jan. 1 Holiday		" 9	49.91
" 2	48.50	" 16	49.33
" 3 Sunday		" 23	48.66
" 4	48.75	" 30	48.65

May	60.21	58.21	Nov.	58.76	49.12
June	59.03	56.43	Dec.	57.73	49.27

The past week's market has been steady, but there has not been much demand from India or China.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Week ending			
Dec. 10	52.50	Dec. 24	53.00
" 17	52.50	" 31	52.50
		Jan. 7	51.50

Monthly averages.

	1913.	1914.		1913.	1914
Jan.	39.37	39.25	July	41.00	37.50
Feb.	41.00	39.00	Aug.	40.50	80.00
Mar.	40.20	39.00	Sept.	39.70	76.25
Apr.	41.00	38.90	Oct.	39.37	53.00
May	40.25	39.00	Nov.	39.40	55.00
June	41.00	38.60	Dec.	40.00	53.10

The average price of quicksilver in 1914 was about $49 per flask, irregular business done during August and September making a true average difficult to obtain. A résumé of the situation in 1914 appears on page 90 of this issue. It is reported that two lots of 1000 flasks each came from Italy to New York since the war started.

TIN

Prices in New York, in cents per pound.

Monthly averages.

	1913.	1914.		1913.	1914.
Jan.	50.45	37.85	July	40.70	31.60
Feb.	49.07	39.76	Aug.	41.75	50.20
Mch.	46.95	38.10	Sept.	42.45	33.10
Apr.	48.00	36.10	Oct.	40.61	30.40
May	49.10	33.29	Nov.	39.77	33.51
June	45.10	30.72	Dec.	37.57	33.60

Tin is quiet at 33 to 34c. per pound. It is reported that a fairly large stock is being held in New York, but not for sale. The possibility of an embargo on shipments from England and the Straits has been discussed.

COPPER

Prices of electrolytic in New York, in cents per pound.

Date.		Average week ending	
Dec. 31	12.75	Nov. 25	12.25 to 12.50
Jan. 1 Holiday		Dec. 2	12.62

May	15.42	13.97	Nov.	15.08	11.75
June	14.71	13.60	Dec.	14.25	12.75

Copper averaged 13.5c. per pound in 1914, against 15.5c. in 1913. Shipments of metal from Michigan in 1914 totaled 53,933 tons, or 107,866,000 lb. The Anaconda output in December was 11,800,000 lb., against 12,700,000 lb. in November. The Company's total in 1914 was about 230,000,000 lb., compared with 271,029,240 lb. in 1913. The Nichols Copper Co., operating a large refinery at Laurel Hill, New York, has passed its quarterly dividend on account of the copper situation. A résumé of the situation last year appears on page 89 of this issue.

LEAD

Lead is quoted in cents per pound or dollars per hundred pounds, New York delivery.

Date.		Average week ending	
Dec. 31	3.80	Nov. 25	3.90
Jan. 1 Holiday		Dec. 2	3.80

May	5.23	4.91	Nov.	5.09	5.01
June	5.00	4.84	Dec.	5.07	5.40

The Joplin market is still strong, and for ore containing 60% metal, the average last week was $51.50, the highest paid being $54.50 per ton.

MAGNESITE

Eastern inquiries for 20,000 tons of California magnesite are reported this week, and a buyer is in the market for that amount.

Pig-iron production in 1914 is estimated by 'The American Metal Market' at 23,200,000 tons, a decrease of 25%; steel ingots, 21,000,000 tons, 30%; finished steel, 16,000,000 tons, 30%; steel castings, 600,000 tons, 40%; and rolled iron, 1,200,000 tons, 28%. Prices at the end of the year were the lowest since 1898, being $13.03 per ton.

There is an increased demand for barium and strontium in the eastern markets.

MINERAL PRODUCTION IN 1914

Preliminary figures of production for a number of the states and metals are given below. Additional figures will be printed from week to week as they be-
silver, and the Survey estimate will be found following his review.
market page.

Anthracite Production

Shipments of anthracite coal from Pennsylvania, as reported by the Bureau of Anthracite Coal Statistics, with those of December estimated, indicate that the quantity sent to market during 1914 was about 68,240,000 long tons, against 69,069,628 tons in 1913. To the shipments of 1914 should be added about 1,000,000 tons, principally of nut and steam sizes, which were stocked in the storage yards, so that while the shipments to market showed a decrease of nearly 1,000,000 tons, the production of the mines was about the same as in 1913, or approximately 81,700,000 long tons, of which 1,800,000 tons was sold locally and 8,650,000 tons used at the mines. The condition of the industry was somewhat peculiar. Consumers throughout the year usually bought for immediate demand, and no more than was necessary. Labor conditions in the anthracite regions are stated as normal. A few strikes of sporadic character occurred, but these have not been of much importance, merely keeping up the interest of the members of the union in the organization.

U. S. Geological Survey Estimates

Coal Production of the United States

Notwithstanding the slough of despond through which the coal-mining industry of the United States was compelled to work its way during the last nine months of 1914, a decidedly hopeful tone prevailed at the end of the year, and the opinion generally expressed to Edward W. Parker was that the receding time had reached its full ebb, and optimism was apparent regarding the coming year. The total coal production of the United States in 1914 is estimated at about 510,000,000 short tons, a decrease of about 60,000,000 tons compared with the record output of 1913. Practically all of this decrease was in the output of the bituminous mines. The production of Pennsylvania anthracite in 1914 was not materially different from that of the preceding year. The principal decreases in the production of bituminous coal were in the coking districts. It is estimated that in Pennsylvania alone the production of bituminous coal decreased between 20,000,000 and 25,000,000 tons, and that the larger part of this decrease was in Fayette and Westmoreland counties, which constitute the Connellsville and Lower Connellsville coking districts. The weekly reports of coke production published in the *Connellsville Courier* indicate that the output of coke in the two Connellsville districts was less than that of 1913 by about 6,000,000 tons, or 30%, and as each ton of coke represents about 1½ tons of coal, a decrease of nearly 10,000,000 tons in the coal output is indicated in these districts alone.

Coal in Ohio

The estimated output of this state last year is 20,000,000 tons, compared with 36,200,527 tons in 1913. A strike and recent legislation worked for this decrease, according to E. W. Parker, the Survey's coal statistician.

Coal in West Virginia

Conditions in the coal-mining industry of this state may be expressed as 'mixed' during the year. Labor troubles, business depression, and other factors resulted in the output being about 70,000,000 tons, against 71,308,982 tons in 1913. The coke manufactured was only about 55% of the previous year.

Coal in the Southern States

The yield of these states was as follows, in tons:

State.	1914.	1913.
Alabama	12,500,000 to 15,000,000	17,678,522
Kentucky	20,000,000	19,616,600
Maryland	4,200,000	4,779,839
Tennessee	5,500,000	6,903,784
Virginia	7,500,000	8,828,068

The business depression made itself felt particularly in Alabama, because of its iron industry.

Coal in the Pacific Coast States

Washington is the only one of any importance, the output being from 20 to 30% less than it was in 1913, when the total was 3,877,891 tons. It is estimated that the consumption of California oil for fuel on the Coast is equivalent to about 20,000,000 tons of coal, or six times the production of Washington.

Utah's Metal Output

As a result of the depression in the metal market due to the European war, there was a decrease of about $6,900,000 in the value of the gold, silver, copper, lead, and zinc output from Utah mines in 1914, according to estimates by V. C. Heikes. Mr. Heikes gives for 1914 a value of $38,000,000. There was an increase in the quantity of lead produced, but decreases in gold, silver, copper, and zinc estimated as spelter. The metal output was as follows:

Production.	1914.	1913.
Ore mined, tons	9,550,000	10,202,566
Gold recovered, value	$3,300,000	$3,565,229
Silver, ounces	11,752,000	13,084,835
Copper, pounds	155,901,000	161,445,962
Lead, pounds	181,553,000	166,126,790
Zinc, pounds	14,297,000	18,857,827

Large Decrease in Metals in Nevada

A decrease in the metal output of Nevada in 1914 of over 22% compared with 1913 is credited to the influence of the European war in lowering the price of the base metals, especially copper. The value of the metal output of Nevada in 1913 was $37,097,000, and the estimate for 1914 is $28,800,000. The yields were as follows:

Metal.	1914.	1913.
Gold, value	$11,320,000	$11,795,130
Silver, ounces	15,200,000	16,090,083
Copper, pounds	60,561,000	90,693,751
Lead, pounds	13,794,000	16,344,023
Zinc, pounds	13,000,000	14,419,671

There was a total of about 2,700,000 tons of copper ore concentrated and smelted.

Metal Output of Montana

The yield of this state in 1914 was seriously affected by the conditions of the copper market due to the European war, as Montana is primarily a copper producer. The value of gold, silver, copper, lead, and zinc from Montana mines decreased from nearly $62,000,000 in 1913 to about $48,000,000 in 1914. The decrease in copper was large, and that in silver was notable, but there were considerable increases in gold, lead, and zinc. The gold recovered increased to a trifle over $4,000,000, or more than for seven years previous. This shows an increase of 14% over 1913, due to dredging and production of silicious ores. Silver decreased from 13,819,201 to

12,000,000 oz., or 13%; and copper from 287,828,699 to 238,000,000 lb., or 17%. Lead increased from 10,935,827 to 15,000,000 lb.; and zinc from 88,673,083 to 109,000,000 lb., or 23 per cent.

Arizona Metals in 1914

The value of the gold, silver, copper, lead, and zinc produced at mines in Arizona in 1914 decreased over 16% compared with 1913, owing principally to the lower price of copper on account of the European war. The estimated output is $59,000,000, compared with $70,875,027 in 1913. There was little decrease, however, in the output of copper, lead, and zinc, and considerable increases were made in gold and silver. The mine yield of gold increased from $4,023,911 in 1913 to about $4,570,000 in 1914. This increase of nearly 14% was almost entirely in silicious ores of gold and silver mines. A record production of silver was made, notwithstanding the reduced market price. The output increased from 3,948,091 oz in 1913 to about 4,469,000 oz. in 1914. While Arizona still leads in copper production, the output decreased, on account of market conditions, from 407,923,402 lb. in 1913 to about 388,000,000 lb. in 1914, a decrease of nearly 20,000,000 lb., or about 5%. The output of lead was practically the same as that of 1913, when the mines produced 16,144,772 lb. The mine production of zinc ore was close to that of 1913, when 14,726 tons of concentrate and crude ore produced 9,428,067 lb. of spelter, chiefly from the Golconda and Tennessee mines in Monave county.

Reduced Production of Portland Cement

According to preliminary returns from all the operating mills in the United States, except one, it is estimated by Ernest F. Burchard that the quantity of portland cement manufactured in 1914 was approximately 88,514,000 bbl., compared with 92,097,131 bbl. in 1913, a decrease of about 3,583,000 bbl., or nearly 4%. The estimated shipments of portland cement during 1914 totaled 86,715,000 bbl., compared with 88,689,377 bbl. in 1913, a decrease of about 1,975,000 bbl., or 2.2%. On account of the surplus of production over shipments, stocks of cement at the mills apparently increased more than 14%, or from 11,220,328 bbl. in 1913 to 12,818,000 bbl. at the close of 1914. It may be necessary to revise downward the figures for stocks, as the estimates furnished by some producers undoubtedly include more or less unground clinker, but it is believed that the figures for production and shipments are very close to those that will be shown later by exact reports from cement producers. Although only general statements as to selling prices are at hand, it is evident that the average value per barrel was slightly lower than in 1913, when the average was $1.005 per bbl. Slight increases in prices are reported from a few plants in the eastern states, but decreases were reported from the majority of plants in all districts.

Production of Copper in 1914

The copper production of the United States in 1914 will show a marked decrease from that of 1913, according to figures and estimates collected by B. S. Butler. Reports have been received from all plants known to produce blister copper from domestic ores and refined copper. At an average price of about 13.5c. per pound, the 1914 output has a value of $152,400,000, compared with $189,795,000 for the 1913 output. The large decrease in production in 1914 was due to curtailment of production during the latter part of the year on account of the reduction in tonnage exported to Europe.

The figures showing smelter production from domestic ores represent the actual production of most of the companies for 11 months and an estimate of the December output. The November figures for a few companies were not available and these companies furnished estimates for the last two months of the year. According to the statistics and estimates received, the output of blister and Lake copper was 1,129,000,000 lb. in 1914, against 1,224,484,000 in 1913. The statistics and estimates indicate that the output of refined copper from primary sources, domestic and foreign, for 1914 was 1,493,000,000 lb compared with 1,615,067,000 in 1913.

According to the Bureau of Foreign and Domestic Commerce, the imports of pigs, ingots, bars, etc., for the first 11 months of 1914 amounted to 187,433,676 lb., and the copper contents of ore matte and regulus amounted to 97,348,866 lb., a total import of 284,782,542 lb. This compares with an import for the 12 months of 1913 of 409,560,954 pounds.

Exports of pigs, ingots, bars, plates, sheets, etc., for the first 11 months of 1914 amounted to 780,048,777 lb., compared with an export for 1913 of 926,441,152 pounds.

At the beginning of 1914 there was about 90,000,000 lb. of refined copper in stock in the United States. This added to the refinery production gives a total available supply of about 1,583,000,000 lb. of refined copper. On subtracting the export from this, with an estimate for December, it is apparent that the supply available for domestic consumption is materially below the 812,000,000 lb of 1913, without taking account of stocks held at the close of the year.

The average price of copper for 1914 showed a decrease from that of the preceding year, being about 13.5c. per pound compared with 15.5c. in 1913. After the outbreak of the European war copper sold considerably below the yearly average, but toward the close of the year the price showed notable improvement.

The leading states were estimated as follows, in pounds:

State or territory.	1914.	1913.
Alaska	20,850,000	23,423,000
Arizona	380,000,000	404,000,000
California	25,000,000	32,492,000
Michigan	160,000,000	155,700,000
Montana	206,000,000	285,700,000
Nevada	60,000,000	85,200,000
New Mexico	60,000,000	50,196,000
Tennessee	18,000,000	19,489,000
Utah	145,000,000	148,000,000

Lead Production a Record

The year 1914 was marked by an enormous increase in the output of domestic lead in the United States, according to C. E. Siebenthal, an increase of nearly 100,000 tons over the production of any preceding year. There was also a heavy decrease in the tonnage of lead of foreign origin treated in the United States, and for the first time in years a great increase in the quantity of domestic lead exported to European countries. At the same time the average price of lead in the United States was the lowest since 1898.

The estimates have been compiled from reports to the Survey by all lead refineries and soft-lead smelters in operation during the year. These reports cover actual production for the first 10 or 11 months of the year, with an estimate for the remainder of the year, and from them the figures of production are made up without change. The statistics of imports, exports, and lead remaining in warehouses have been taken from the records of the Bureau of Foreign and Domestic Commerce for 11 months, the figures for December having been estimated.

The production of refined lead, desilverized and soft, from domestic and foreign ores in 1914 was approximately 537,079 short tons, worth at the average New York price $41,892,162, compared with 462,460 tons, worth $40,696,480, in 1913, and with 480,894 tons in 1912. The figures for 1914 do not include an estimated output of 12,850 tons of antimonial lead, against 16,665 tons in 1913 and 13,552 tons in 1912. Of the total production, desilverized lead of domestic origin, exclusive of desilverized soft lead, is estimated at 312,257 tons, against 250,578 tons in 1913 and 221,480 tons in 1912; and desilverized lead of foreign origin comprised 25,295 tons, compared with 50,582 tons in 1913 and 88,377 tons in 1912. The production of soft

lead mainly from Mississippi Valley ores is estimated at 199,527 tons compared with 161,300 tons in 1913 and 191,614 tons in 1911, the largest prior output of soft lead. The total production of lead desilverized and soft, from domestic ores, was thus about 511,784 tons, almost 100,000 tons more than in any previous year, and 25,000 tons more than the total output of the country from both domestic and foreign sources in any previous year.

The imports of lead are estimated at 11,764 short tons of lead in ore, valued at $743,332; 14,998 tons of lead in base bullion, valued at $1,029,233; and 142 tons of refined lead, valued at $9751, a total of 26,904 tons, valued at $1,782,316, compared with 37,145 tons, valued at $2,965,817, in 1913. Of the 1914 imports about 20,000 tons, or nearly 75%, came from Mexico, against 47,847 tons in 1913 and 79,728 tons in 1912, the decrease being due to domestic strife in that country. From Germany came 2265 tons, from German East Africa 1278 tons, and from Chile about 1250 tons.

The exports of lead of foreign origin smelted or refined in the United States again show a big decrease, being estimated at 21,193 tons, against 54,323 tons in 1913.

For the first time in years there were exports of domestic lead to Europe, the total for the year being estimated at 62,924 short tons, valued at about $4,804,000.

The amount of lead available for consumption during 1914 was 442,744 tons, which, compared with 419,463 tons in 1913, 388,148 tons in 1912, 385,319 tons in 1911, and 379,196 tons in 1910, and taking into account trade conditions during the year, seems to be an excessive figure, making it seem very probable that there has been an increase in lead stocks. Of the foreign lead remaining in warehouses at the close of November 1914, there was at El Paso 2176 short tons and at New York 4846 tons, with small quantities at Chicago and St. Louis. The average New York price for the year was 3.9c. per pound, compared with 4.4c. in 1913 and 4.5c. in 1912.

Quicksilver in 1914

By Clifford G. Dennis

Production and Development

During the year 1914 the quicksilver production of the United States was approximately 20,670 flasks of 75 lb. each, valued at $1,017,171; an average value per flask, based on monthly averages, of $49.21. California produced 16,571 flasks, and Arizona, Nevada, and Texas 3099 flasks. The production up to August 1 was at a rate far below that for 1913, in which year the lowest production for years was recorded. In August the price of the metal reached the highest since the early days of quicksilver mining in California, and many operators whose plants were closed on account of poor market conditions, started up. At the year's end the production is estimated to have exceeded that for 1913 by 989 flasks and $343,117 in value.

The average price, computed from monthly averages, for the first seven months, was $38.70 per flask, and for the last five months $63.80 per flask. The approximate production and monthly averages are given below.

Month.	Flasks.	Per flask.
January	1320	$39.25
February	1601	39.00
March	1482	39.00
April	1683	38.90
May	1592	39.00
June	1720	38.60
July	1506	37.50
August	1467	80.00
September	1877	76.25
October	2230	53.00
November	2103	55.00
December	2089	55.00

Production 1899 to 1914 (Incl.)[sic]

Year	Cal. flasks.	Texas flasks.	Others flasks.	Total metric tons	Value
1899	29,451	261		1,925	$ 1,[illegible],700
1900	26,417	1,700	233	974	1,[illegible],430
1901	26,720	2,932	75	1,031	[illegible],300
1902	29,552	5,252		1,208	1,[illegible],744
1903	32,091	5,029		1,288	1,564,734
1904	28,876	5,436	700	1,204	[illegible],184
1905	24,655	5,000	1,050	1,045	1,217,652
1906	19,516	1,517	1,276	861	1,[illegible],138
1907	17,532	3,000	400	712	[illegible],678
1908	16,969	2,832	346	685	903,391
1909	16,217	1,188	810	701	941,283
1910	18,536	3,382	500	763	1,054,991
1911	18,860	2,396	....	732	989,254
1912	20,600	2,700	1,847	855	1,067,742
1913	15,396	....	4,285	670	774,054
1914	16,571	....	3,099	703	1,017,170

The price of the metal was low during the first part of the year, but the demand was fairly good. In August the price was bid up, presumably by foreign buyers, to phenomenal figures. One small lot of 20 flasks was bought and paid for with cash at the mine at $110 per flask. During these very high prices in the United States, the price quoted at London remained the same, about £7. Later the London quotation has been above the American quotations.

California.—The New Idria, in San Benito county, continues to lead California producers, although this mine has been running far below the record for 1913. Extensive developments are said to be under way that will make available a large tonnage of low-grade ore that will be of commercial value when these developments are completed. At the Aurora mine, in the New Idria district, experiments with a rotary furnace have been under way, thus far without results. The operators expect some returns early in 1915. The Oceanic mine, in San Luis Obispo county, has experienced a successful year, under the management of Murray Innes. The furnace has been supplied with ore principally from old stopes. New developments in the lower levels are said to have been disappointing, but lateral work on the adit level has been most encouraging. At the Guadelupe mine, in Santa Clara county, extensive developments have been under way, which are said to be most successful. The New Almaden furnaces, under the management of W. H. Landers, have operated this year entirely from old dumps, surface croppings, and from refuse about the furnaces. The reorganization of the Quicksilver Mining Co., which owns these mines, has been retarded on account of the financial conditions, but it is expected that during 1915 a vigorous campaign of development will be put under way. At the Helen mine, in Lake county, most of the year has been spent doing development work. The St. Johns mine, in Solano county, has been operating in a small way since June 1.

The Cambria Quicksilver Co., while an important producer from 1906 to the end of 1908, was then idle until October 1914. Since that date, 15 men have been engaged in prospecting and development. An orebody has been found, and if it proves sufficiently extensive the 50-ton furnace now on the property will be put into operation early this summer.

Texas.—The Chisos mines, at Terlingua, Brewster county, had considerable difficulty in securing labor owing to the nearness to the Mexican border. It has been reported that these mines will be equipped with additional furnace capacity in 1915.

Arizona.—The Sunflower district reported a new body of ore, also a discovery was reported from Gila county. No further activity was reported by the Cinnabar Development

Co. that was operating the Colonial mine in west central Yuma county.

Nevada.—The Mercury Mining Co., at Ione, Nye county, closed down its furnace early in the year, and development was continued under the direction of W. E. Goldswarthy. Sufficient ore was opened so that the furnace could be started again in the fall. The Nevada Cinnabar Co. put its 50-ton furnace in operation early in the year and has experienced a successful year under the management of John Andrews. At the Goldbanks property, operating near Winnemucca, a set of 15 inclined pipe-retorts was erected. Later this set of retorts was discarded and replaced with a 10-ton, inclined, 10-muffle retort. The muffle is arranged so that it may be charged and discharged a carload at a time, making the treatment continuous. This Company has made and burned 360,000 common brick and is preparing to erect a furnace in the spring. A new furnace was not erected at the Ruby mine last year as reported. Treatment of the high-grade ore was continued in the pipe-retorts and further development carried on. A new furnace is planned for 1915. A 10-pipe retort was erected at the Dalbare mine, which is situated at the southerly end of the Humboldt mountains.

METALLURGICAL IMPROVEMENTS

Hearth Furnaces.—Considerable discussion has arisen of late, among operators, regarding the hearth type of roasting furnace, as to its application to quicksilver ores. There is no doubt that these roasters can be adapted to roasting quicksilver ores, and the saving and condensation of the fumes accomplished successfully. The ore would probably be roasted more rapidly than in the Scott type of furnace, and with the application of fewer heat units per ton of ore treated. The first cost of almost any of the hearth furnaces would be less per unit of capacity than the Scott, and it would be better adapted to intermittent service. The operating cost of the hearth type would probably be higher. Such furnaces would require a higher class of labor to operate than the Scott, would be liable to cause long delays on account of repair parts, and would have a considerably shorter life.

Whether the fixed charges against a hearth type furnace, being less on account of smaller investment, would offset the increase in operating expense, is a question. It is difficult to estimate what the maintenance of one of these furnaces would be, for the reason that all available costs are based on operating several of the furnaces in one plant, thus reducing the maintenance cost to the minimum. The question is, what would the conditions be if one of these furnaces were placed away off from the source of supplies, how much skilled labor would have to be kept on tap for emergencies, and what would the delays caused by lack of parts and time securing same, cost?

The matter of reducing the investment is important, for it is evident that the average furnace outlasts the life of the average mine, so that a small increase in operating cost against decreased investment would ultimately work out in favor of the hearth type of furnace. On the other hand, the Scott furnace is almost 'fool proof,' can be counted to deliver day in and day out, and the maintenance cost is small.

Flotation.—Some experiments that I made on flotation as applied to cinnabar ores may be mentioned. The mineral occurred in a soft decomposed tufa, too soft to run through a furnace, and was of such low specific gravity that very low capacity could be obtained in any type of furnace. The experiments determining the cinnabar floats very readily. An extraction of 92% was obtained by running the pulp through the machine twice. It is not likely that similar conditions exist in many places, therefore it is not likely that flotation will ever take an important part in the metallurgy of quicksilver. On the average cinnabar ore, it would be cheaper to roast the ore direct.

A Wet Process.—The excessive loss of mercury in 'high-grade' treatment at the Buffalo Mines at Cobalt led to careful studies of possible methods of recovery and development of a process for wet treatment. Details of the process have not been made public as yet, but experiments on mercury ore are said to indicate the probable availability of the process for general purposes. Details are promised later.

U. S. Geological Survey Quicksilver Estimates

According to preliminary figures collected from individual producers by H. D. McCaskey, the output was 16,568 flasks, valued, at the average price at San Francisco of $49 per flask, at $811,832. This is a decrease of 3645 flasks and $1339 in value compared with the previous year. There were 33 mines worked, against 24 in 1913. California showed a decrease of 4122 flasks. Arizona, Nevada, and Texas yielded 477 flasks more than in 1913. Exports during the past two years were 452 in 1914 and 1140 flasks in 1913; and imports, 9140 in 1914 and 2290 flasks in 1913.

Zinc Estimates Not Available

The U. S. Geological Survey has found it impossible to obtain estimates of output and stocks of zinc for 1914 from a number of producers. It is not likely that any statistics of zinc output will be published until the Survey's annual chapter on zinc from 'Mineral Resources' is made public.

MINING DECISIONS

MINERAL OIL AND GAS NOT 'FRUITS OF THE LAND'

The statutory right of a possessor in good faith of land to reap the benefit of the fruits of the land until it is claimed by its owner, does not permit such possessor to extract the mineral oil and gas from the land and retain the proceeds.

Elder *v.* Ellerbe (Louisiana), 66 Southern, 337. November 16, 1914.

COAL LEASE—LESSOR NEED NOT OWN LAND AT TIME OF LEASE

In an action by the lessor to recover stipulated royalties under a coal lease, the defense made was that the lessor did not own the land at the time he leased it. Held, that inasmuch as the lessee was given possession under his lease, and no fraud, accident or mistake in its execution alleged, or ejectment of the lessee by the owners of the land or surrender of the lease to the lessor, or covenants against defective title proved, the recovery of royalties could not be defeated.

Lazarus *v.* Lehigh Wilkes-Barre Coal So. (Pennsylvania), 92 Atlantic, 121. July 1, 1914.

PLACER LEASE—CONSTRUCTION

Where a lease of mining ground required the royalties to be paid during the year, the whole amount of the annual rent matured at the end of the year, and, if not paid, an action would lie, whether the rent was payable in money or in gold dust. If the lease did not specify the place of payment, it is presumed that they were payable on the premises and omission to designate a place of payment is no defense. Where such a lease provided for work steadily from the date of the lease, weather and season permitting, a custom that, in the absence of a contrary provision, the lessee might cease work whenever he chose was irrelevant. In case of a breach by nonperformance of such working conditions, the lessor is neither required to enter and work the ground or re-let to another as a condition to recovery of damages from defaulting lessee.

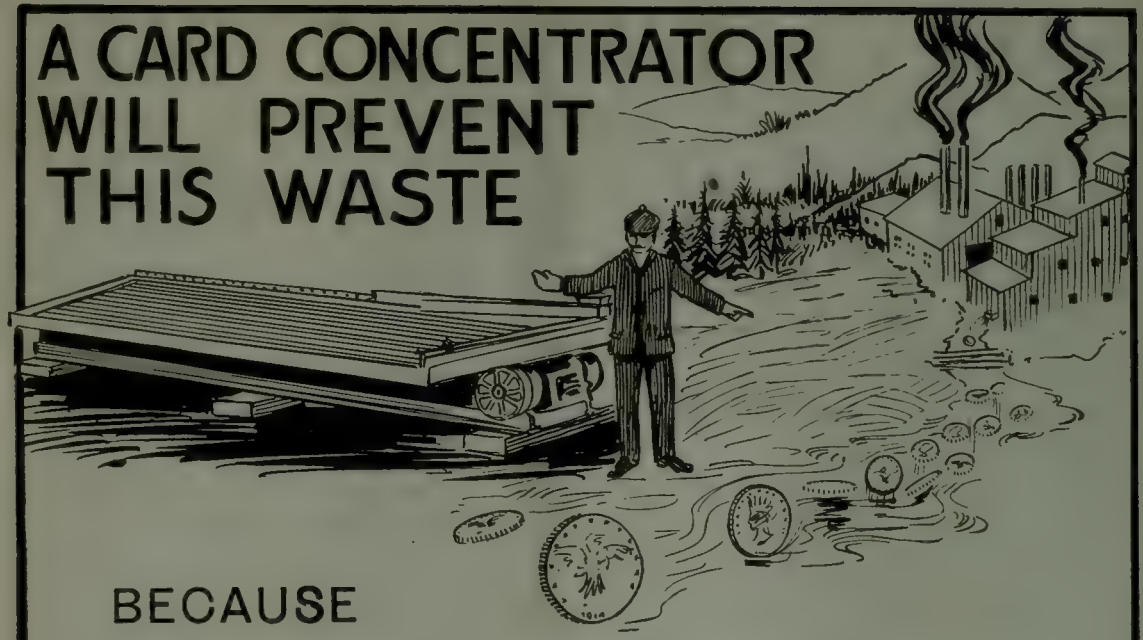
A New Industry In an Old Country

INDIA is thought of by most Westerners as a large country densely populated by very poor people, among whom are a few brilliant philosophers hopelessly wedded to abstract studies. It has long been known as the 'sink of silver.' Ages of misrule have made the native distrustful of any but tangible wealth that may be hidden, and the amount of silver held in India is enormous and beyond positive knowledge. Lately India has been absorbing gold. Having taken 20 per cent of the world's output in one year, it is clearly a country of larger real wealth than generally appreciated. Now a new condition has arisen. Under stable government the people of India are laying aside their mistrust, and under the wise guidance of far seeing leaders, such as Messrs. J. N. Tata and B. J. Padshah, India is bringing her money out of hiding and setting it to work. This is a phenomenon of more interest to the West than the mere shipment of a few thousand tons of pig iron annually. A great modern iron and steel works has been put in operation. It was built and is officered by American engineers, but the workmen, the capital, and the initiative came from India itself. It is a genuine expression of the determination of the leaders of India to re-establish the ancient industries of their country. How carefully and how wisely it was planned is told most interestingly in this number by Mr. Weld.

A CARD CONCENTRATOR WILL PREVENT THIS WASTE



BECAUSE

It makes the least possible quantity of middlings and delivers a classified product of concentrates across the entire width of its front end.

The 'Card' is so well and favorably known, is in successful operation in so many mills, on so many varieties of ores, in all mining districts of the world, that an extended description is unnecessary.

However, our "*Card Catalog*" gives dimensions—speeds—capacities, etc., as well as description, and you should have it in your library. Write for it now while you have time. A postcard will bring it.

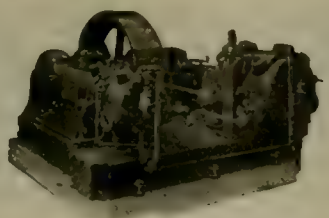
Sullivan Liteweight Water Drills.

Sullivan Angle Compound Air Compressor.



Sullivan WJ Air Compressor.

Sullivan "DI-33" "Rotator."

Sullivan Drills and Sullivan Air Compressors have been selected by all the contractors for driving the St. Louis Intercepting Sewer Tunnel.

This tunnel is to be 18,000 feet long and 19.5 x 19 ft. in section. The excavation has been let in three sections, to three independent contractors.

The tunnel-driving equipment purchased by these three firms for this work comprises:—

6 Sullivan Belt-Driven Two-Stage Air Compressors, five having a piston displacement of 1015 cu. ft. per min. each, and one having a piston displacement of 628 cu. ft. per min.

46 Sullivan "FF-12" 2⅝-in. Liteweight, water attachment Rock Drills.

8 Sullivan "Rotators."

Why not specify Sullivan Equipment for your next Shaft or Tunnel?

ARTICLES

LOOKING FORWARD 96

In an interesting address before the American Mining Congress, Mr. W. G. Swart pointed out that prospecting and development are two different things, and that, whatever might be true of the former, the latter needed stimulation. In this, mining engineers should be leaders. Small companies had already proved that, by conservative action and adoption of the principle of distributed risk, a good business could be built up.

BEGINNINGS OF THE TATA IRON & STEEL COMPANY OF INDIA.

By C. M. Weld 97

India was one of the countries in which iron working began, but in recent years it has been an inconsiderable producer. J. N. Tata, a wealthy and patriotic Parsee merchant, who established cotton spinning in that country, undertook to re-establish the iron and steel industry. Being disappointed in the first deposits brought to his attention, he commissioned Mr. Weld, acting under Mr. C. P. Perrin, to study the whole field and find the best place in India for establishment of works. This was done, and a fine modern plant is now delivering high-class product. Mr. Weld tells the story of the survey with its disappointments, peculiar difficulties, and final triumph.

TUBE-MILL PEBBLES—THEIR CHARACTERISTICS AND COST.

By Edwin C. Eckel 103

In order to compare tube-mill pebbles as to efficiency, it is necessary to determine the physical and chemical properties essential to them. This Mr. Eckel does, bringing out especially the importance of their specific gravity. He then considers the various materials available in the United States and elsewhere, and their relative efficiency. Mr. Eckel is an engineer particularly familiar with the portland cement industry and speaks from wide observation and study.

MINING IN BRITISH COLUMBIA DURING 1914.

By W. M. Brewer 104

Contrary to predictions, British Columbia mines did fairly well in 1914. The total decrease in output as compared with 1913 was 14 to 15%, and the total output worth $26,000,000. The big event of the year was the opening of the Anyox smelter of the Granby company

MAGNESITE DEPOSITS AND POSSIBILITIES IN CALIFORNIA.

By Samuel H. Dolbear 105

Inquiries for magnesite have been pouring upon California producers since the war checked imports, and inquiries have also poured in on the *Press*. In response to request, Mr. Dolbear has written briefly but accurately regarding the trade in general, production and uses, grades, and California sources of magnesite. The industry is one that warrants further development.

STAMP-MILL TEST.

By E. S. King 109

Abstract from *The Mining Magazine* of a record of a test between Nissen and Sandycroft stamps, made at Tincroft, Cornwall.

THE HARDENING OF METALS 112

Note on an address by Sir Robert Hadfield delivered before the Faraday Society.

DEPARTMENTS

DISCUSSION:

Amalgamation in Hardinge Mills.

By F. J. Girard, M. W. von Bernewitz 110

Mr. Girard raises some questions over contradictory results at Plymouth and Incaoro. Mr. von Bernewitz speaks of experience in Australasia.

Valuing Placer Ground. *By Edmund Bonella* 111

A further contribution to the discussion running in the *Press* through the past several months.

Precision of Thought. *By J. Nelson Nevius* 112

One man, at least, who agrees with the editor.

CONCENTRATES 113

MINING IN THE FAR NORTH.

The Outlook for Quartz Mining in the Fairbanks District. *By Emil Edward Hurja* 114

Lode mining at Fairbanks is still an industry of small units, but there are many of them. Mr. Hurja gives some account of virtually all.

DREDGE TAILING from Natoma is being tested at the Plymouth mine as a substitute for tube-mill pebbles.

EMBARGO on the export of ores, concentrate, and metals from Australia to the United States has been lifted by the Commonwealth government, provided the authorities there are satisfied that these products will not be transshipped to any of the countries at war with England.

TUBE-MILL pebbles have received but little systematic study, though all users know that they vary greatly in value. Mr. E. C. Eckel's discussion will, therefore, be received with especial interest. We shall follow it with a more elaborate study by Mr. Jay A. Carpenter of the pebbles he has been using at Tonopah.

SUIT is to be begun at Los Angeles next Monday to recover for use as a naval reserve, oil lands in the Elk Hills region now held by the Southern Pacific and claimed to have been acquired as agricultural lands by fraud. This is considered to be the strongest of the various cases that the Washington authorities have, and much will hinge on the decision.

AT the meeting of the San Francisco section of the American Institute of Mining Engineers, held at the Engineers Club last Tuesday evening, the proposed amendments to the constitution were discussed at length. At the close of the meeting a call for expression of opinion showed that among those present, some twenty members, the sentiment was unanimously in favor of the amendments.

ALIEN labor laws received a setback last week when the United States District Court of Arizona, sitting at San Francisco, held the Arizona statute unconstitutional. It was held that if an 80 per cent restriction could be enforced, any other percentage up to the whole could be equally well applied. This introduces discrimination, against which the laws guarantee both citizens and aliens. The case has been appealed to the United States Supreme Court.

OUR attention has been called to an error in the statement of the outstanding first debenture bonds of the Mond Nickel Company, Limited, which amounts to £375,000, and not £3,750,000. The mistake was in the original cable. The total of the old and new bond issues is £875,000, not a large amount for a company possessing such excellent properties as the Mond company holds, particularly when the able management of the concern is taken into account.

FIRMS in neutral European countries complain that in addition to other handicaps they are unable in instances to buy American goods because the foreign agencies are lodged in London, and for any one of several reasons the British firms handling the business are not prepared to sell or ship. Evidently this war will lead to readjustments of foreign trade far more numerous than is even yet realized. Neutrality without commercial independence is less valuable than it sounds.

A CYNICAL onlooker replied recently to the question, what, in view of present unfavorable conditions, mining engineers would have to do to make a living, by remarking that he was afraid they would have to go to work. The Mexican troubles, coupled with the European war, have hurt mining engineers as much as any class of professional men. Mr. W. G. Swart, in the address of which we present an abstract this week, points out one way that they may occupy themselves to advantage.

ESTIMATES of gold-silver production of the various states, as made by the Bureau of the Mint and the U. S. Geological Survey, are presented on another page. It is comforting to note that there has been a substantial increase. The silver output was one of the greatest yet realized, despite the disorganization of markets in the latter part of the year. Demand from India and China was disappointingly small and stocks accumulated, but on the whole, the year's results were better than had been feared.

MAGNESITE, chromite, manganese, and many other of the minor minerals found upon the Pacific coast are now in exceptional demand, owing to disturbance of usual trade relations by the war. We present this week a discussion of the California magnesite industry, written by Mr. Samuel H. Dolbear, a chemical engineer who has gone into the active work of production, and who brings out a number of points not generally understood. This article will be followed by others of similar character giving information greatly in demand at the present time.

MINERAL EXHIBITS of the United States and some foreign countries will be displayed in the Palace of Mines and Metallurgy of the Panama-Pacific Exposition. Those from Australia and New Zealand will only be shown in the respective buildings of those countries, which are situated in the grounds near the Presidio. The war, in which these British possessions are taking an active part, has caused a considerable reduction in the extent of the buildings and exhibits as originally planned. However, good samples of rocks, ores, metals, rare earths, and gems, with mine models and other interesting features of the industry which has produced approximately £810,000,000 in Australia and £125,000,000 in New Zealand, will be on view.

SOME of the difficulties of mining operations in European countries, even in districts outside the war zone, are reflected in the report of the Chairman of the Board of the Tanalyk Corporation, who relates that the first mobilization of the Russian army took away the manager of the mine and smelter, three mining engineers, the chief chemist, thirty-five members of the office and administrative staff, and nearly one-third of the workmen. The second and third calls for men made a further reduction in the working force. Fortunately, a nine months' supply of ore for the smelter was already on the stockpile, and ore reserves had been developed much in excess of the daily requirements, so that even if the war should last four years, the present smelter unit can be kept in operation. The Tanalyk has made an excellent showing to date, and it is pleasant to be able to record that recent exploration indicates that several additional valuable orebodies can be developed.

COMPLAINT of unfair exactions of ore buyers is as old as the trade, and it is not likely that it will altogether cease so long as ore is sold. It is to be remembered, however, that similar criticism is leveled at buyers of other commodities, and is apt to continue until human nature changes materially. One of the most vigorous protests we have seen was published recently in *The Norwood Post*, and relates to carnotite buying in Colorado. Mr. Frank Silvey shows that the producer receives but $145 per ton, and must wait five to six months for the greater part of that, for ore in which the uranium and vanadium content is worth $939. Allowing for losses and transportation, Mr. Silvey estimates the ore as worth $734. Such figures are deceptive, since there is no apparent allowance for treatment and since, furthermore, the market for both uranium and vanadium is extremely uncertain. None the less, there is doubtless foundation for the charge that in this trade the middleman has, as is the custom of middlemen, exacted large profits. In view of the wide difference of opinion that exists as to the policy, and the criticism that has come from Colorado against the Bureau of Mines going into radium refining, it is interesting to add that both Mr. Silvey and *The Norwood Post* look upon government purchase of the ore as the only solution.

CHINA has been considerably affected by the war, directly and indirectly. The decline in silver and the consequent fall in exchange since the start of the war would, in normal times, tend to stimulate exports and curtail imports; but the demoralization of financial and shipping facilities, and the falling off in the European demand for China's most valuable exports, namely, silk, tea, hides, skins, and beans, has, until recently, according to a *Commerce Report* of November 5, resulted in an almost complete cessation of shipments to markets that formerly absorbed a large portion of the country's production. In consequence of the loss or restriction of outlets for native articles, the purchasing power of the Chinese has been seriously curtailed, while the rapid decline in exchange has increased the difficulties of the situation. Prior to the war, the value of the Shanghai *tael* was, in United States money, about 65 cents, compared with 53 cents early in November. During the same time the value of the Mexican dollar, which is the coin that is actually in use, has declined, in terms of *taels*, from 73.3 to 71.85. This is due to the fact that the natives are receiving almost no money against export cargo that they have to sell, and the country merchants are sending down dollars from the interior. The amount from any one place is not large, but the total receipts of those added to a stock of dollars at Shanghai that was already large has depressed the price. This means that up-country buyers have to pay more for any purchases they may make, and naturally this has a tendency to restrict their buying. When these interior points become over-drained of actual money, the pendulum is likely to swing the other way; furthermore, the lower the dollar rate goes the more likely is the up-country holder of produce to be able to dispose of his stock at a price that must find a market for it.

THE ENGINEERING CONGRESS AND MINING MEN

Mining engineers have been strangely slow about joining the International Engineering Congress which is to be held at San Francisco in 1915. Although the American Institute of Mining Engineers is one of the five societies underwriting the project, less than 300 mining engineers have, as yet, sent in their applications for membership. Despite the fact that many thousand circular letters have been sent to mining men, it seems probable that there is some misapprehension as to their relations to the Congress. Membership in any or all of the five great societies that have organized the latter, does not include membership in the Congress itself. On the advice of the governing boards of the societies, the Congress was organized independently and upon the basis of individual memberships. The parent societies have merely guaranteed expenses up to certain agreed amounts, to which total has been added some $11,000 raised by engineers on the Pacific coast. It is hoped to pay the necessary expenses of organizing and directing the Congress and of publishing the proceedings, in large part at

least, from membership fees, and to return to the societies the money advanced by them. Each member of the Congress is charged $5, which entitles him to participation and to receipt of the general or index volume of transactions and to any one of the other volumes that he may select. Additional volumes may be purchased at prices fixed to cover the cost of publication. No engineer will receive any volume unless he becomes a member of the Congress and pays the necessary fee.

While the program of the Congress has been somewhat disarranged by the war in Europe, it will none the less be comprehensive and fairly complete. In general, it is planned that the series of papers shall, as a whole, depict the present state of the art in the various branches of engineering. It is expected that the volumes will constitute a working encyclopedia of present practice and a datum plane for all future investigations. The subjects to be included range from the Panama canal as a concrete example of modern engineering, through waterways and irrigation, railways, municipal engineering, materials of engineering construction, mechanical engineering, electrical engineering, mining engineering, metallurgy, naval architecture, and marine engineering, to educational and miscellaneous topics. It was originally planned to print 10 volumes, but, owing to the withdrawal of papers from Germany, and to a less extent from other countries now busy with other matters, the number will probably be reduced to eight. The topics relating to mining and metallurgy that will be discussed are: economic and social influence of mining; valuation of mines and prospects; valuation of oil lands and properties; exploration and development; financing mining properties; organization of operating staffs; the government and mines; mine inspection; mine taxation; metallurgy of iron and steel, of copper, of zinc and cadmium; cyanide practice; lead smelting and refining; metallurgy of minor metals; metallography; electro-metallurgy; utilization of fuels; ore dressing. Each topic has been assigned to a prominent engineer, who, in most instances, is acting essentially as the chairman or sub-editor for the section, assembling data secured through co-operation of many fellow workers. Among those who have accepted this responsibility are Messrs. W. H. Shockley, W. W. Mein, R. V. Norris, M. E. Lombardi, Sidney J. Jennings, A. Chester Beatty, D. C. Jackling, H. V. Winchell, J. A. Holmes, J. Parke Channing, H. M. Howe, E. P. Mathewson, W. R. Ingalls, C. W. Merrill, H. O. Hofman, W. W. Campbell, E. F. Roeber, C. H. Fulton, and R. H. Richards. This by no means exhausts the list, since not only are many engineers and metallurgists actively co-operating with the men mentioned, but many topics under other heads, such as materials of engineering construction, are being treated by men equally well known to the mining profession, including Messrs. Thomas T. Read, E. C. Eckel, C. K. Leith, and others. Both the meetings themselves, which will be held September 20 to 25 inclusive, and the printed volumes will be well worth the attention of any mining engineer who cares to keep in touch with his profession in a broad way. It is important that each should realize that the papers are now coming in and that plans and contracts for printing must be made now. In order to act intelligently, the committee in charge must know what measure of support to expect from the mining engineers as well as from others. If you have mislaid or lost the application blank already sent you, send word to the International Engineering Congress, 1915, Foxcroft building, San Francisco, and a duplicate will be sent. The important thing is to act promptly.

THE RUBBER FAMINE

In the discussion of British interference with American trade, the attention of mining men has been so concentrated upon the acute troubles of the exporters of copper and importers of cyanide, that the danger of a famine in rubber, among other things, has been largely overlooked. The situation was discussed briefly by our New York correspondent last week, but its importance warrants a few words more. Briefly, the larger portion of the rubber now used in the United States normally comes from plantations within the British Empire. Much of it is handled in London, but some is sold direct. England has laid an embargo on all rubber exports and has so far refused either to raise it or to state that it will be maintained for any definite period. The result is that crude rubber has been piling up at London, Singapore, Colombo, and in Canada, and selling in London at 51 cents per pound, while in New York it commands 87 to 91. Furthermore, a considerable part of the accumulated stock had been bought and paid for by American manufacturers in the normal course of trade, who now find themselves unable to bring in their own rubber. The estimated consumption in the United States for 1915 is 65,000 tons. There is available in this country and Brazil but 35,000 tons. A shortage is inevitable, but even if manufacturers accept the situation and plan to pass on the increase to the consumer, they must face risk of the embargo being raised and the market flooded after they have stocked up and before they are able to sell their manufactured products. Vigorous protests have been made at Washington, but, so far, without satisfactory results. There is a suspicion, how well founded we are unable to say, that the British government desires to exact as compensation for permitting export to the United States, a *quid pro quo,* which Washington is unable or unwilling to give. Mr. B. G. Work, of the Goodrich Rubber Company, has gone to London on behalf of an American committee to consult direct with British rubber handlers in an effort to find a *modus operandi.* It is sincerely to be hoped that an amicable adjustment may be promptly found, since one of the alternatives suggested is an act forbidding any importations of rubber or rubber goods from the British Empire so that the uncertainties hanging over the manufacturers may be removed. The mining industry uses large quantities of rubber, and the interest of mining men in this situation is therefore far from being academic.

LOOKING FORWARD

In the course of an interesting address on 'The First Move,' delivered before the recent meeting of the American Mining Congress, Mr. W. G. Swart made some pertinent constructive suggestions. After pointing out that there was a general impression that the lucky prospector finds a mine ready made, he showed that what was usually found was a 'prospect,' that is, simply the surface indication of possible ore beneath. It generally takes both time and money in liberal amount to ascertain whether this is of possible value, and this is 'development.' It is the part of mining which involves the greatest risk and offers the greatest reward. It is distinct from prospecting, though that fact is not generally understood by the public. "Mining," Mr. Swart said, "is more apt to suffer from lack of development than from lack of prospecting." Continuing, he said:

In spite of all unfriendly criticism of pretensions to see underground, use of yellow leggings, or partiality toward offices in the high buildings, the fact remains that nearly every successful mining operation of consequence, old or new, is today in the hands of experienced technically trained men. These are the men who select, who reject, who discriminate, who decide on the place, time, direction, and amount of expenditure, and who plan and execute the work. No man does these things for any considerable time successfully without becoming a business man of high order. Leadership is his by every right.

In one of the classes recently graduated from a certain mining school were four young men who resolved to pool their efforts and go to mining directly, instead of accepting salaried positions as assayers or surveyors. At the end of five years they are in far better financial condition than the average of their classmates, they have had more real experience, and they understand what accepting responsibility means; but above all, they stand absolutely at the head of mining affairs in their community and are reaching out steadily for larger things. They have made good, and in making good they have secured an unhesitating local following in every mining enterprise they will take over. This is the kind of leadership I have in mind. No irresponsible promoter can capture that community. The one necessary thing is to guide and systematize local activity, and it can be done properly only by the trained men. They must first show confidence in themselves, then build up the confidence of the community in their ability, integrity, and unselfishness, and the rest is easy.

A company of ten engineers was recently organized in Colorado with modest capital, and this company is already successfully operating selected properties. When these men began systematically to put faith behind their works and money behind their judgment, they took the first necessary step. They have already secured the confidence and following of the communities in which they operate. No one believes that ten experienced men can be seriously misled, or that they will ever adopt anything but a policy of absolute fairness and integrity. Everyone believed they would win, and they have.

While this is not the place for details, it may be well to point out briefly several interesting features of this first move: (1) The proposal is not that the movement be restricted to mining engineers and operators—simply that it must be organized and directed by them. (2) The movement probably cannot succeeed without the confidence and co-operation of the business and professional men of the respective communities. Mining has usually been only a side issue, an incident, a speculation, if you like, with most such men. Investing without proper guidance, their activity has been spasmodic and unsatisfactory. (3) The movement must not only be started, but be made systematic and continuous, otherwise it has no real future. (4) The organizers must be prepared to make sacrifices of time and energy, to say nothing of money, and to sink any petty professional jealousies; but at the same time the idea must not be allowed to creep in for one moment that it is in any sense a philanthropic move. There can be just one underlying aim, and that is to make mining pay. (5) No such organization can hope to succeed permanently which does not propose to be fair and more than fair to its non-technical associates and stockholders. The plan rests solely on confidence in the ability and fairness of technical men. It is useless to start on any other basis. (6) It is not expected nor necessary that every engineer and operator take an active part in such an organization; some are overburdened now; some are honorably bound to organizations already existing; some are more efficient working alone; but there is plenty of available material in every mining district. (7) It is a 'get together' plan with indirect as well as direct benefits. (8) It requires no large amount of capital. It is better to start modestly and well within the means of the primary associates. It is particularly necessary to assume no financial responsibilities beyond the actual capital in sight. Success in even the smallest way brings possibilities of growth far faster than they can be properly cared for. A good set of brakes is more essential than the high gear. (9) The mining men will have to start this themselves. No one is going to do it for them. No one ought to do it for them.

This paper is not an inquiry into what is wrong with mining. It suggests that if something *is* wrong with mining, here is one constructive remedy. This is a workable plan, details of which will vary with location and conditions. It is already in successful operation, but it is possible only to a body of trained men. Undoubtedly there are other good methods, but, as I see the situation, the underlying idea must be the same in all: the qualified mining men ought to be in better control of the industry than they are; and they can be, but the first move is theirs.

Beginnings of the Tata Iron & Steel Company of India

By C. M. WELD

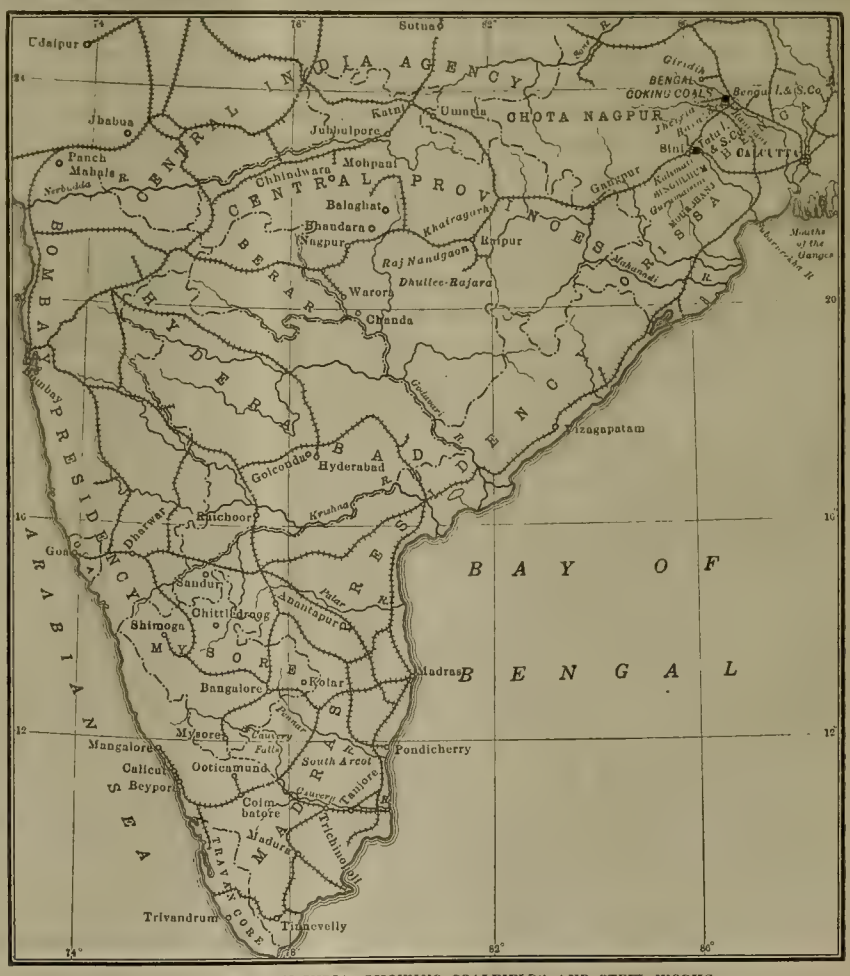
Recently from time to time the trade journals have discussed a threatened invasion of our Pacific coast by Indian pig iron; as a matter of fact, one small shipment has actually reached Seattle. Large amounts of this same iron have of late years been shipped to Japan and to other markets in the Far East. Whether or not the markets of our Far West will likewise be invaded is an open question, and one not within the scope of this paper to discuss. This pig iron comes from the works of the Tata Iron & Steel Co., Ltd., situated in Bengal, British India, 155 miles west of Calcutta. The works include by-product coke ovens, blast-furnaces, steel furnaces, and rolling mills, with all accessories. A number of descriptions have been published in the trade journals and need not be supplemented here. (*Iron Age*, July 12, 1906; September 28, 1911; April 11, 1912; January 13, 1913. *Iron Trade Review*, September 23, 1909; July 23, 1914.) An assembled view of the plant as it was in 1911, when practically completed, is shown on pages 98 and 99.

It was my good fortune to be intimately connected with the early history of this project, and it is thought that the following notes, dealing with its beginnings and the manner of its gradual development, will be of interest. I propose to tell the story from a human and personal point of view rather than from a technical one.

This project was by no means the first attempt to make iron in India. The existence of iron ore in that country has been recognized for many centuries, and in times past a flourishing native smelting industry existed. It is said that the famous Damascus swords were manufactured from bars of Indian 'wootz' or steel, made in the Deccan (Hyderabad) and transported by caravan across Persia. The forged iron column discovered in recent years at Delhi is another monument to the skill of these ancient ironmasters. Even today, a few hundred tons of iron annually is produced in nearly as many little mud blast-furnaces, blown with goat-skin bellows, scattered about remote parts of India, more particularly in the jungles of the Central Provinces. By way of contrast with the Tata works, one of these native furnaces is shown on page 101. A brief description of a village of native smelters was published by me some years ago. (*Iron Age*, September 13, 1906.)

The earliest attempt to make iron in India by European methods was due to Josiah Heath of the Madras civil service, who constructed small charcoal works at Porto Novo in the South Arcot district of Madras Presidency, in 1830. This industry was continued by the Porto Novo Steel & Iron Co., and later by the East India Iron Co., other works being erected at Beypur on the Malabar coast and in the Coimbatore district. All came to an end about 1867 after an intermittent and unprofitable existence. Further unsuccessful attempts along similar lines were made in Chota Nagpur and in Kumaun.

In 1874 a small blast-furnace was built at Barakar,



MAP OF SOUTHERN INDIA, SHOWING COALFIELDS AND STEEL WORKS.

THE COMPLETED WORKS OF THE

in the Raniganj coalfield, to run on coke fuel and iron ores from nearby ironstone shales. This furnace ran intermittently, at one time under the direction of Ritter von Schwartz, until 1890, when it was scrapped. At that time it had produced about 43,000 tons of pig iron, at a financial loss.

First Successful Iron Making

The next year marked the beginning of the only successful iron venture in India up to the time of the Tata project. A new and larger furnace was built at Barakar on the site of the first furnace, and was run on the same raw materials. A second stack was added in 1899. In 1903, the Barakar Iron & Steel Co. had produced about 250,000 tons of pig and castings and had made money. Shortly after, a heavy loss was suffered through an ill considered attempt to make steel; this was soon abandoned, and the Company has since recuperated its losses and has added to its blast-furnace plant. Hematite ores from Singhbhum are now drawn upon in conjunction with the leaner high phosphorous local ores; flux comes from Sutna, 500 miles distant, and coke is obtained from the neighboring coalfields.

The Tata project first began to take definite shape in 1902, although it had been brewing for some time before. Other projects were broached at about the same time. In 1899, an elaborate report by Major R. H. Mahon, R. A., 'Upon the Manufacture of Iron and Steel in India,' was published by government, wherein a plant to produce from 300,000 to 400,000 tons annually and to be placed near Calcutta was recommended; ore was to be drawn principally from Madras, coke from Bengal coalfields, and flux from Burma. Investigations were also being carried out in behalf of the Right Honorable Sir E. Cassel, based on certain iron ore deposits near Jublulpore. Neither of these prospects came to anything.

J. N. Tata, a wealthy and philanthropic Parsee merchant of Bombay, head of the firm of Tata & Sons, was particularly well known in the Central Provinces on account of the enormous success of his cotton mills, situated at Nagpur. The Central Provinces were reputed to be rich in iron ores and were known to contain coal. Many years before, in 1882, Ritter von Schwartz had reported favorably upon a proposal to manufacture charcoal iron in Chanda district of the Central Provinces. Certain government officials brought the matter before Mr. Tata and aroused his interest. Coal and iron ore concessions were granted to him, and in 1902 he came to Europe to employ technical advice for carrying out his plan. By chance he was turned from Europe to America, and ultimately employed C. P. Perin of New York. Mr. Perin carefully studied his various documents and advised him against building an iron and steel plant till far more was known about his concessions. I was selected to examine the latter, and reached India on this mission in January 1903. One Bravo diamond hand-drill had been sent out ahead of me.

I proceeded at once to Chanda district, where I found the drill already at work a few miles south of Chanda on the coal concession; in charge of a former government irrigation engineer. The latter had had absolutely no experience with diamond-drilling. He had dropped his tools in the hole, and, being more ingenious than practical, was experimenting with an impromptu invention which he called a microphone to find their top. I spent two days vainly fishing, the hole having partly filled with sand. I then started a shaft to recover the bit, which I knew to be not more than 30 to 40 ft. beneath the surface, and while this was going on, I investigated the concession. From distant outcrops and government boreholes on a neighboring area, I determined that the coal was not less than 700 ft. deep. As the capacity of the drill was at most 350 ft., I abandoned the drilling. I got samples of the coal from the nearest openings and found it to be a stratified material, high in ash, and absolutely non-coking.

Then I investigated the iron ore deposits. In this and in all of my subsequent work I was most efficiently helped by a nephew of Mr. Tata, Shapurji Saklatvala, who acted as interpreter and in many other capacities. The deposits were situated from 15 to 50 miles east and southeast from Chanda. We toured the jungle, travel-

TATA IRON & STEEL CO., LTD., IN 1911.

ing on horseback, with our camp equipment in bullock carts. Needless to say, progress was exceedingly slow. I examined a number of deposits and found several of these rich but of apparently limited extent. This was later confirmed by some exploratory work.

In the meanwhile I visited other coalfields in the Central Provinces and central India, at Warora, Mohpani, and Umaria. The product of all of these was found to be non-coking. Therefore, after two or three months' labor, I made an adverse report to Mr. Tata in relation to the proposed iron and steel plant based on Chanda iron ores.

Mr. Tata was disappointed. I then learned what I had not known before, that while naturally requiring the proposed scheme to be a sound one financially, he further looked upon it as an opportunity for developing a big industrial training school for the natives of India. It was in this direction that he was more particularly disappointed, and he was very loth to give up the project. The upshot was that I was commissioned to develop, if possible, a feasible project for the manufacture of iron and steel in India, irrespective of its locality.

My work henceforth was on far broader lines. My first care was to learn where coking coals could be obtained, and I soon determined that only those of the Bengal coalfields, and indeed not all of those, would yield good metallurgical coke. This was afterward fully confirmed by thorough coking tests.

We then started on an iron ore campaign, the hope being to discover large bodies of rich ore, accessible in themselves and at the same time reasonably near the Bengal coking coals. I first toured considerable portions of the native states of Nandgaon and Kairagarh, looking up reported ore deposits, and then located a deposit of great promise in the western part of Raipur district. This work carried me through the hot season into the rains, when it was necessary to abandon horses and bullock carts and take to light traveling on elephants, owing to the heavy condition of the roads and jungle tracks, and the swollen streams. Elephants could generally be borrowed from the native rajahs, who were glad to help, for their keep and the pay of their attendants.

Really excellent maps, on the scale of one inch to the mile, are available for large portions of India. It was my practice at this time to study these maps with great care, searching for places with names related to the vernacular words meaning iron or iron working. I found many such and visited them, or sent native assistants. I was able to obtain good assistants, trained in geology at the geological school of the state of Mysore. I also employed untrained scouts who had been taught merely to recognize the heavy 'black stones.' Of course I met with frequent disappointments, but together we covered and eliminated in this way large areas.

During the rainy season of 1903 we got out three more Bravo diamond-drills. We opened the fall campaign of that year by establishing the four drills on the promising deposits discovered in the western part of Raipur, in the Dhullee-Rajara hills; in charge of an experienced drillman sent out by the Sullivan Machinery Co. The orebodies, in lenticular form, cropped along a tortuous ridge, extending for several miles and rising about 400 ft. above the general level of the surrounding country. Our drills were placed along and near the outcrop of the ore, and the necessary water supply at once became a problem, especially since every hole promptly lost its water. The nearest spring was about two miles away, at the foot of the ridge. At first we tried pack-bullocks for carrying water, but ultimately we fell back upon coolie women and the omnipresent five-gallon kerosene can. We employed nearly a hundred women on this work. A group of these women is seen on the following page, as is also a drill at work.

Fighting Mosquitoes

Our Dhullee-Rajara explorations developed large bodies of exceedingly rich ore. Incidentally we had a serious experience at this camp with the anopheles mosquito, and learned, too late, that the most vicious of his kind in India is a little brown fellow who rarely sings, and breeds among grasses along the banks of running

WATER COOLIES AND DRILL CREW.

streams. The work of our staff was continuously crippled by malarial fever; a fact which was the more unfortunate because a little more knowledge and experience would have enabled us to avoid much if not all of this sickness.

In the meanwhile continued field reconnaissance along the lines described above in many other quarters, principally eastward, failed to develop any other ore deposits of promise; and when the Dhullee explorations were completed, I had about concluded that our proposed iron and steel project must be predicated upon these Raipur ores in conjunction with Bengal coke. The fuel and ore were over 500 miles apart, but under the circumstances it was concluded that this was not prohibitive. I therefore set about determining upon the best site for assembly of the raw materials and their manufacture into finished products.

In relation to this inquiry we had many factors to consider, one of great importance in India being water supply. During the nine dry months, from the middle of September to the middle of June, all but the largest streams go practically dry, the river beds turning into great wastes of sand. Then, too, existing railway lines, relative distance from markets, the hitherto undetermined source of flux, the distances of the several raw materials in relation to their importance, and questions of available cheap land, foundations for heavy structures, labor, and climate, all had to be taken into consideration. A thorough search for suitable flux was undertaken, and the Bombay office investigated with great care and thoroughness the iron and steel markets of India. A number of possible sites were studied and rejected. Also the Bengal coalfields were carefully gone over and large samples were taken and shipped to Europe and America for washing and coking tests.

All these various investigations, following upon the iron ore campaign, carried us well into the hot season of 1904. In the meanwhile, to our great sorrow, J. N. Tata, the initiator and the soul of the enterprise, had died. The work was, however, taken up by his two sons, Sir Dorab and Ratan Tata, almost as a matter of inheritance, and pushed with as much vigor as before.

It was in May of 1904, when we were winding up our work and preparing to submit the results to the expert criticism of Mr. Perin, that we first heard of the existence of iron ore in the jungles of Mourbhanj state. It was then too near the rains to start a new field campaign, and I sent my native assistant geologist to make a brief reconnaissance. He examined the Gurumaisini deposit, and made so favorable a report that we promptly arranged for concessions covering this new find and revised all our plans regarding point of assembly and manufacture so as to admit this new source of iron in conjunction with our proved-up Raipur ores.

SURVEY PARTY IN CAMP, FEBRUARY 1908.

WOMEN COOLIES AT WORK.

METHODS OF TRANSPORTATION ON SURVEY, AND NATIVE IRON FURNACE.

I then went home, taking with me four volumes of reports, statistics, and maps resulting out of our 18 months' labor. On the way I conducted elaborate washing tests on the large samples of Indian coals sent to Germany, and later we made coking tests in America on the samples which had been sent there.

The following January 1905 I was back in India, this time with Mr. Perin. Together we examined the Mourbhanj ores, which we found even better than we had hoped. We also visited the coalfields. As a result we presented a joint report recommending an iron and steel industry to be situated at Sini on the Bengal Nagpur railway, to run on Bengal coke and Mourbhanj ore. It was understood that land was available, and that any one of several good damsites near Sini would serve to impound sufficient water to carry the plant through the dry season.

Here, I may say, ended the first chapter. The project remained in *statu quo* for over two years, vain efforts being made in England and elsewhere to float it. Finally during the summer of 1907, in the heat of a patriotic movement, known as the Swadeshi, whose object was to encourage home industries in India, capital was raised for the proposed iron and steel plant almost overnight and entirely among native Indians. The new Company was named the Tata Iron & Steel Co., in honor of J. N. Tata, the founder of the enterprise.

I was called back to India—I was in China at the time—and arrived in November 1907. Work had been started at Sini, but unexpected difficulties had been encountered, first with the purchase of land (not only for the works, but also for the reservoirs), and secondly with the foundations for the dams. After going over the field once more most carefully, I selected a new site a few miles eastward, just north of Kalimati station, on the Bengal Nagpur railway. Here we arranged to expropriate about four square miles lying between the railroad, the Kharkai river, and the Subarnrekha river, and we secured a 25 years' lease on an additional tract of about 20 square miles. We found a good place for a pick up weir in the Subarnrekha river, where a more resistant trap dike stood out above the river sand, forming almost a natural weir; and an excellent site for a supplementary reservoir in the hills just north of the river. Foundations proved to be sound, and good deposits of brick-clay were at hand.

On Christmas day of 1907 we pitched our first tent on a site which I had selected for our construction camp, near the native village of Sakchi, lying about two miles north of Kalimati and close by the Subarnrekha river. My assistant at this time was B. B. Willcox. We immediately assembled a corps of native engineers under the direction of K. R. Godbole, and by the end of January, when Axel Sahlin of Julian Kennedy, Sahlin & Co. (who had been appointed construction engineers), arrived on the ground, with his resident engineer, W. O. Renkin, we had already contoured a large area. Work on grading began at once, and before May there were several thousand coolies, men, women, and children, at work.

From this time on, my connection with the enterprise gradually diminished. I spent one more winter in India, working up the raw materials end of the enterprise and many other matters not directly in the hands of the construction engineers. A general manager, R. G. Wells, was appointed and came out in January 1909, and I made haste to turn over my duties to him as soon as practicable. As representative of the consulting engineer, my position was now somewhat anomalous, and my earlier experiences in India, while roughing it in the jungle, had not contributed to my health.

Furnaces Put in Blast

The plant grew in due course to its present proportions under the direction of Kennedy, Sahlin & Co., the first blast-furnace being blown in December 1911. The second followed in September 1912, and the steel furnaces a few months later. Marked commercial success has already been attained, and the great works, flanked by a town of several hundred bungalows and coolie lines, with water supply, lights, ice plant, soda water factory, institute for the hundred or more Europeans, bazaars and recreation grounds for the several thousand natives, etc., all sprung up out of the jungle in the course of a few years, stand as a lasting monument to the far-seeing and progressive enterprise of a single broad-gaged Parsee merchant. His dream of a great successful industrial works, and with it a great industrial school for the natives of India, has been consummated.

To me, however, the accomplished fact is not so full of fascination as the formative period, with its long months of work and study, the weary days in the jungle, the many disappointments, and the exhilaration of occasional successes. I fear the foregoing sketchy account

will have conveyed a very inadequate idea of the immense scope of our investigations, the ground we covered, and the thoroughness, largely due to B. J. Padshah, with which we did it all. At the last we felt that whatever might be the intrinsic merits of our scheme, at least we had the best that could be devised for India; and it is a matter of satisfaction to all those connected with its development to see it succeed.

The Native Point of View

As supplementing the various technical descriptions which have been published from time to time and already referred to, I append a description translated from a Bengali weekly paper of April 1910.

"It is known to all now that Tata & Co. are having a steel factory in the district of Singhbhum, close to the Kalimati station on the B. N. railway. This is the outcome of the late J. N. Tata's whole life toil. Had he been spared to live now, we know not how his heart would have glowed with joy. The seed of his indomitable perseverance for the fruition of which he traveled the world over is now about to grow into a tree. We call it ours—because it is Swadeshi, and we wish it all success.

"The name of Kalimati has spread far and wide among the working classes, and the name having excited my curiosity, I proceeded there on leave to see the grand new project. Luckily I met a friend of mine who had been staying there for over a year, and I felt no inconvenience during my stay with him; rather I could see all that is going on there, in detail—the big iron foundry, the wonderful cooling tank, the new half-built town, the murrum roads, all of which tended to please my eyes. The place is a charming one, being rich with natural scenery in all directions. Here the two rivers, Subarnrekha and Kharkai, flow at the foot of a range of high hills. Tata & Co. have purchased this vast tract of land through the government from the Midnapur Zemindary Co., Puttnidars under the Dhalbhum raj.

"The contract for the building of this factory has been given to an American company of engineers known as Julian Kennedy, Sahlin & Co., who, as I understand, are to have a 5% commission on the total expenditure. This Company has posted one sahib by the name of W. O. Renkin, whose messing expenses are, I hear, borne by the Tata company. He is a competent man and has kept everything under his thumb, so much so that none can or has the courage to even put in a peg in his absence. There is a general manager here by the name of Mr. Wells. He is an expert in iron works and has been brought out on a high pay. Since his arrival the work is making a rapid progress, and in fact he has finished almost half the work in four or five months; he has an amiable look about him. There are many more Americans occupying various other posts, the details of which I propose to publish at length in a future issue.

"But how is this? It is an Indian concern. Mr. Tata took so much pains all his life in order to teach his own countrymen, but instead of that we see foreigners have crowded in. In such a big factory I could not find a single jewel of India. Has not Bengal, Bombay, Madras, Punjab, and the United Provinces produced a son who is fit to work in the Tata's factory? All this sight is depressing my heart and I am afraid lest this also turns into the same darkness it was in before. After spending so much money, if your countrymen do not get a place there in the factory from the beginning, God alone knows what is to happen in future."

What of the Future?

This is interesting in giving us a native point of view, which I may say is no doubt fairly generally held. In the meanwhile the management and directorate, who are themselves natives, are in fact working in the direction suggested, namely, that of replacing European with native talent, but are making haste slowly, and are well advised in doing so. Already J. N. Tata's ideal of a native industrial school has been realized, but it would be particularly unwise in a venture of this sort to promote the scholars into the places of their teachers with undue haste.

THE COMPLETED FURNACES.

Gold and silver received at the San Francisco mint in December amounted to 227,571 and 126,141 oz., respectively, with a total value of $4,779,888. Coinage executed was $1,075,000 gold, 31,200 nickel, and ₱106,000 silver for the Philippines. Coin, bullion, etc., on hand at the end of the year was as follows:

Gold coin	$ 15,972,800.00
Silver coin	61,716,089.51
Nickel coin	48,161.10
Bronze coin	12,129.85
Checking balance, Treasurer United States	649,678.45
Gold certificate bars	140,453,529.97
Gold bullion	39,866,996.53
Silver bullion	918,788.60
Total	$259,638,174.01

Gold output of the Mt. Boppy mine, New South Wales, in November, was $57,600 from 6631 tons of ore. The leaching plant treated 1314, and the slime plant 4388 tons respectively.

Tube-Mill Pebbles—Their Characteristics and Cost

By EDWIN C. ECKEL

Ever since the tube-mill first came into extensive use as a fine-grinding machine in the portland cement industry, there has been a wide interest in the character and source of the pebbles that are or can be used as grinding media in this type of mill. More recently, the adoption of the tube-mill in many gold and other ore-concentrating plants has increased the number of engineers to whom this subject is of interest. Most recently of all, the European war has given an immediate interest to the question, since it threatened to raise difficulties in the way of securing the flint pebbles which had been the most important part of the supply. Under these circumstances, a discussion of the present and probable future sources of the pebble supply for tube-mills, and of the character of materials available for such purposes, is justified.

Before the different types of pebbles which are available can be compared, it is necessary to come to some conclusion as to the physical and chemical properties which such pebbles should possess, in order to be serviceable for the tube-mill. The main factors may be summarized as follows:

Shape.—To secure the maximum of grinding efficiency, the pebbles or other media employed should be as nearly spherical as possible.

Size.—Other things being equal, the maximum grinding effect is probably secured by small pebbles, which give more grinding surface per ton of pebble.

Density.—Other things being equal, a dense or heavy pebble will grind more effectively than a pebble of lighter material. In practice it may be assumed that the materials ground, in cement or metallurgical practice, will have specific gravities about as follows: cement clinker, 3 to 3.15; dense trap, etc., 2.9 to 3.1; granite, gneiss, etc., 2.6 to 2.8; limestone, 2.3 to 2.9; shale, 2.1 to 2.6; and sandstone, 2.1 to 2.7.

As will be seen later, these materials are being ground with flint or quartzite pebbles in most cases, and sometimes with granite pebbles. Flint, quartzite, and granite all range around 2.6 to 2.8 in specific gravity, so that in many cases the pebble used is lighter than the material undergoing the grinding. It is obvious that in such cases there is a loss in grinding effect, which might conceivably go to the point of grinding up the pebbles faster than the ore or clinker.

Toughness and hardness.—What has been said as to the advantages of a heavy pebble must not be allowed to cover the fact that in general practice the most important physical properties are toughness and hardness, in the order named. The pebble should be harder than the material to be ground; and it should also be tough, for otherwise there will be a heavy loss in breakage of pebbles, with reduced efficiency as a result for a time at least.

Chemical composition. Since the pebble, no matter how tough and dense it may be, is finally ground and enters the mixture, its chemical composition is of interest in some cases. An iron ball will increase the iron content of the ground material, and in some metallurgical work this is undesirable. Nearly all of the natural pebbles are either almost pure silica (flints, quartzites, etc.) or high in silica (granites and other igneous rocks), so that the natural pebbles will increase the silica content of the mixture to some extent. This does not matter when cement is being made, as the addition of finely ground flint or granite will improve it rather than otherwise. Still, there will be some instances where the composition of the pebble is a matter of moment.

Cost per ton of pebble and product.—The various pebbles will show different costs per ton of pebble, at most points where they are to be used; and this will enter into the question of comparative availability. But generally, particularly if chemical composition is of no importance in the decision, the availability will be determined, not by cost per ton of pebble, but by cost per ton of ground ore or cement.

Having summarized the characteristics which are desirable in a tube-mill pebble, different kinds of pebble material which are actually available in most regions may be compared. This can, of course, be done in only a general way, as each locality should be studied as a separate problem; but there are some general features which serve to limit or indicate the choice that can be made.

Flint.—Flint pebbles were the first materials used in tube-mills, and still furnish the bulk of the supply, so that they must be taken as a basis for all comparison. Flint is very tough, so that the pebbles will wear down smoothly without much breakage. In composition they contain from 80 to 95% silica, as shipped, which does no particular harm in cement manufacture or in most metallurgical practice. As against these advantages, flint is lighter than most ores or cement clinker, and in most regions it is expensive per ton of pebble. Since the whole supply is imported, and no large water-worn deposits of flint are known to exist anywhere in North America, flint pebbles are expensive at most interior points. Several cement manufacturers have estimated that flint pebbles are about 50% more efficient, that is, more durable, than the next best pebble available in any large tonnage; so that considerable difference in cost per ton of pebble can be allowed before flint can be displaced on the Atlantic seaboard. Elsewhere, however, freight rates soon make up for the original advantage.

Quartzite.—Next to flint, a fine grained quartzite probably ranks second in all-around efficiency. The quartzites are somewhat harder than flint, and of essentially

the same chemical composition. They are, however, less tough, and a charge of quartzite pebbles will show a greater percentage of broken fragments at the end of any given time than would a charge of flint pebbles. Quartzite pebbles are abundant along the Lake Superior and Newfoundland coasts, and are marketed now on a moderate scale.

Granite.—Granite and the other acid igneous rocks are less hard than quartzite, and usually are deficient in toughness, breaking along a more or less apparent grain in the rock. Granite pebbles occur along the New England and Newfoundland coasts, and could be made an article of commerce. They also occur in many western stream valleys, and have been used for over 10 years by at least one California cement plant.

Trap.—The basic igneous rocks of the type of trap are usually somewhat softer than either quartzite or granite; but they are, on the other hand, often tougher and more durable, and they are notably heavier than any of the other types of pebbles. Basic pebbles are found in quantity at certain points on the Lake Superior and Newfoundland coasts, as well as in many stream valleys in the interior. To my knowledge they have not been used in any cement plant.

Mining in British Columbia During 1914

By W. M. BREWER

All things considered, the end of 1914 shows that the mining industry in British Columbia has not been affected as much by the war in Europe as many of the best authorities predicted. An estimate made carefully and conservatively by the Provincial Mineralogist gives the total decrease below the returns for 1913 as being between 14 and 15%. The total production, including all metals and minerals, for that year was reported in the Report of the Minister of Mines at the value of $20,296,398, while the estimate for 1914 is $26,000,000 in round figures. It should be remembered that the value of the production for the year 1913 was the greatest for any, except 1912, since the discovery of placer gold in Cariboo in 1852, and according to the estimate the year 1914 will only fall about $6,000,000 short of the banner total value, less than 20 per cent.

The most notable event in the mining industry in this province during the year 1914 was the 'blowing in' of the Granby company's smelter at Anyox, Observatory inlet. The Company has expended nearly $4,000,000 in development of the mines and construction of the smelter, power plant, docks, railway, buildings in both the smelter and mining camps for all of the employees as well as for the Company's purposes, and water and sewer systems. The fact that operations have been continuous since the furnaces were put in blast in March speaks volumes for the future prosperity of the enterprise. When a company is able to continue active operations during a period of such unusual disturbance in business, with so many enterprises closed, it is *prima facie* evidence that under normal conditions the results will be highly satisfactory.

The production from the placer mines in the Cariboo and Cassiar mining districts, which include Atlin, Quesnel, Omineca, Dease Lake, and Barkerville, is estimated at $500,000 for 1914 as compared with $560,772 in 1913. The production of lode gold, silver, copper, lead, and zinc will be about $14,000,000 during 1914, as compared with $17,700,838 in 1913. In connection with this decrease it must be remembered that the market price of each of the metals except gold has been considerably lower during 1914 than it was during 1913; in fact, the lower market price will account for $1,250,000 of the decrease in the value of the production.

The value of the production of coal and coke for 1914 is estimated at about $9,000,000, as compared with $9,197,460 for 1913. There are two reasons for this, the first being the decreased demand for coke at the Trail and Boundary smelters owing to the closing down of the Granby and Mother Lode plants at Grand Forks and Greenwood and the part closing down of the Trail plant at the commencement of the war; the second being the disorganized conditions of labor on Vancouver island following the strike during 1913. It is gratifying to be able to announce at the beginning of 1915 that on Vancouver island the collieries are running at their normal capacity, and that the Trail and Granby plants are running almost up to capacity, so that the new year is commencing under favorable auspices.

The value of miscellaneous productions such as building stone, gravel, and sand, is estimated to reach $3,000,000 for 1914, or about the same as for 1913, when it was stated in the Report of the Minister of Mines at $3,398,100. Although the building industry has been quiet in the province during the past year, as it has been the world over, yet the enormous quantity of broken rock used in the construction of the breakwater and piers at Victoria has at least offset the decreased quantity of building stone used in 1914 as compared with the quantity used in 1913.

The prospects for the coming year, despite the continuance of the war in Europe, can be considered to be fairly bright so far as the mining industry is concerned in British Columbia, as there are good prospects that some properties hitherto unknown as producers will have reached the stage of development that will place them in the lists of shipping mines, and among these should be properties along the line of the Grand Trunk Pacific railroad. Lack of transportation facilities has retarded development in that part of the province tributary to the Skeena river, where there are several promising gold-copper, as well as silver-lead, and silver-lead-zinc properties partly developed. Some of these are within a short distance of the new railway, in fact within less than three miles from established stations, and but 500 to 1500 ft. higher elevation. No great investment of capital is needed to place them in a position to ship ore to a smelter.

Magnesite Deposits and Possibilities in California

By SAMUEL H. DOLBEAR

At the outbreak of the war, inquiries for thousands of tons of magnesite poured into the mails of the owners of California magnesite deposits.* Austria-Hungary leads the world in the production of the commodity, its exports to the United States alone amounting to about 143,000 tons in 1911, about 100,000 tons in 1912, and 172,500 tons in 1913. As the United States imported only 4880 tons in 1911, 3834 tons in 1912, and 8876 tons in 1913 from other sources, it is readily apparent why the participation of Austria-Hungary in hostilities led American consumers of magnesite hastily to seek other sources. California is the only one of the states producing magnesite, and its greatest output in 1910 was less than 13,000 tons. Practically the entire production is consumed on the Pacific coast, and the largest portion is shipped to the paper mills of Oregon and Washington. The limitation of its sale to the Pacific coast has been due primarily to the high freight rates prevailing to eastern points and the high cost of labor at the mines. Lower freight rates through the Panama canal should assist the California producer materially in reaching eastern markets. Wages for labor of all classes are, in most cases, higher on the Pacific coast than in other parts of the country, and the influx of Europeans through the canal would, it has been believed, eventually reduce labor charges to a more normal basis. In the meantime, the flames of war are being fed with the blood of thousands of peasantry who might otherwise emigrate into this country, and any radical change in the labor situation will doubtless be long delayed on this account. With these two factors innuring to his advantage, the California magnesite producer should be in a position to command a portion of the present import consumption.

*In all the following paragraphs, the word magnesite should be taken to mean the calcined product, unless otherwise specified.

Uses of Magnesite

The highly refractory quality of magnesite and its ability to form a hard vitreous body when combined with magnesium chloride has led to its adoption for a large number of purposes. The largest consumption is in the manufacture of magnesite firebrick, crucibles, and in bedding steel furnaces. As magnesium bisulphite it is used extensively in digesting and whitening wood pulp in paper mills. It is used in a mixture with sand, sawdust, ground quartz, talc, and other substances, in the manufacture of tile, plastic flooring, roofing, sinks, wainscoting, in scagliola or artificial marble, and on the exteriors of buildings as a plaster. The manufacture of so-called 'cold water' paints and concrete waterproofing also involves the use of magnesite with $MgCl_2$. It also enters into a preparation for insulating boilers and steam pipes, mixed with such substances as asbestos and infusorial earth. It has been introduced into boilers to prevent scale when sulphurous water is used.

A misapprehension exists that there is no market whatever locally for crude magnesite. I am aware of at least three carloads which have been taken within the last two or three years by local steel manufacturers. This ore is crushed to pea size and mixed with the calcined product. Less amounts are consumed by the dynamite manufacturers, and some is ground to a fine mesh with buhrstones for use in preparation of tooth-paste. In times past, finely crushed magnesite has been sold as chicken grit. Small amounts, finely ground, are sometimes used in oxychloride mixtures and as an adulterant in paint. Of late, certain dealers in photographic supplies have tried to persuade local magnesite shippers to undertake the manufacture of metallic magnesium, offering to contract for their entire consumption for a period of two years.

Much magnesite was formerly burned for the double purpose of securing a calcined product and to recover

SWINDELL MAGNESITE MINES AND WORKS.

FRESNO MAGNESITE CO. AT PIEDRA.

the carbon dioxide content. The reason which led to a discontinuance of this practice was that efficiency in the production of one product was had at the expense of the other. The magnesium oxide residue contained variable quantities of carbon dioxide, and when the rock was burned with care, difficulty was experienced in securing a maximum yield of CO_2 for the period. For several years limestone has taken the place of magnesite, although recently attempts have been made at a carbonic-gas plant situated at Berkeley to revive the practice.

The plastic floor industry has grown to considerable proportions within the last few years. When properly mixed and laid, magnesite makes an excellent floor, it having many advantages not possessed by other materials. It takes a good polish, is fireproof, waterproof, and will not dust. Unfortunately, however, it is never certain that a good job is going to result, and in many cases magnesite floors have bulged, cracked, and have required complete relaying. This is due, in all probability, entirely to chemical differences in the mixture. The presence of lime (CaO) in too large a quantity always results in failure, although it has been suggested that climatic conditions may influence the success of the set. The business has suffered many reverses and adverse criticisms through the work done by irresponsible workers who understood little of the mechanical practice of oxychloride cement and nothing of the technical side. It is worth observing that those who understand the work, use care in selecting their materials, and stick faithfully to formulas which have been found most successful, have only occasional failures. Magnesite used in plastic work usually carries from four to eight per cent carbon dioxide.

California magnesite is purer and consequently more refractory than that of Austria-Hungary. The latter product carries variable amounts of iron which reduces its point of fusibility. In spite of this fact, the iron-bearing variety is preferred for use in steel furnaces. At a given temperature, the magnesite becomes plastic and may be molded into place, and later sets or hardens. I have never seen any attempt made to explain this fact, but it is perhaps through the formation of a double salt of magnesium and iron.

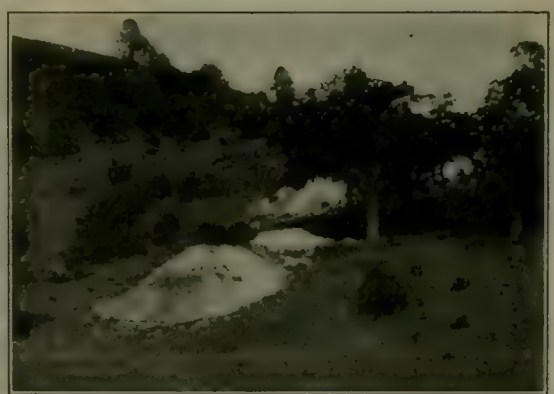
Calcined magnesite when exposed to air takes up carbon dioxide. A statement has recently been made that it will completely carbonize in six months. Such a statement should not, of course, be given credence. A gain of 10 or 15% CO_2 in that period would be large under circumstances favorable to its recarbonization. Nevertheless, there is every advantage in the use of a freshly calcined product both in steel practice and plastic work. Too much CO_2 renders it entirely unfit for floor work, and when placed in a furnace a loss of 10% CO_2 represents a shrinkage of an equivalent cubic amount, leaving patches in the bed to be refilled.

Prices

The price which has been paid for domestic magnesite has varied from $16 per ton on contract for large quantities f.o.b. rail at the point of shipment to as high as $50 for small lots of a ton or two ground and packed in barrels at San Francisco. Normally the price for carload lots unground in bags is $25 to $30 per ton and $40 per ton for the ground product in barrels. Light burned magnesite has been recently offered for local consumption, ground, in barrels, at $35 per ton f.o.b. San Francisco. At the outbreak of the war, Chicago consumers of light burned magnesite offered to contract for 1000 tons, unground, in barrels weighing 300 to 400 lb., at $33.50 per ton, f.o.b. rail California. Some European product is again coming into this country, and somewhat lower prices prevail. Quotations f.o.b. New York are now from $30 to $35 per ton.

Magnesium Chloride

As the industrial uses of magnesite, aside from its refractory applications, are dependent largely upon the ability to secure magnesium chloride, a word regarding this product should be said. In San Francisco, the fused or crystalline chloride in iron drums is normally sold at $22.50 to $25 per ton ex-shipside. Practically all the chemical used in this country comes from Germany, where it is produced as a by-product in the manufacture of potash from the Strassfurth deposits. At



CEDAR MOUNTAIN BEFORE DEVELOPMENT.

the opening of the war, prices soared to $60 per ton with little apparent supply. Eastern consumers, foreseeing a famine of German product, wired to California urging that it be produced here and offering to purchase in liquid form in tank cars. This action stimulated investigation, and experiments have been conducted along three different lines: (1) that of direct production from magnesite and hydrochloric acid; (2) that involving the use of dolomite as a source of magnesium; (3) through the recovery of $MgCl_2$ from the bitter brines of local salt works. These bitter brines contain as high as 17.8% $MgCl_2$ at 30 Baumé. Shipments from Europe are again coming into this country, and recent tenders are at a price of $27.50 per ton f.o.b. New York in carloads, which is equivalent to about $40 per ton at California ports.

Magnesium chloride has been manufactured in limited quantities in San Francisco and Alameda by dissolving magnesite with hydrochloric acid. No attempt was made in either case to reduce it to a crystalline form. It is said to have cost about $24 per ton, the price being estimated on a crystalline basis. In one case this was done to secure a colorless product, as the magnesium chloride of commerce is frequently badly discolored through the presence of iron rust.

California Production and Sources of Magnesite

Tulare Mining Co.—For several years the Tulare Mining Co. has been the largest individual producer in California. Its production is used largely by the paper manufacturers of Oregon and Washington, the magnesite company being a subsidiary of the Willamette Pulp & Paper Co. The deposits of this Company are on the south fork of the Tule river and about ten miles east of Porterville in Tulare county. A spur track two miles long connects the mine with the Southern Pacific railroad, and from a point of transportation makes this mine more easily operated than other deposits in the state. Much development work has been done on these deposits, and an apparently large body of ore is exposed. The mine is equipped with a vertical or stack calcining furnace, having a capacity of 500 or 600 tons per month, and this furnace is worked continuously at about 80% of its capacity. Two grades of magnesite are produced, one of selected white rock for plastic use, and another somewhat discolored through the presence of iron. The calcined product is placed in sacks, a portion of the output being shipped to San Francisco, ground and barreled, and sold to local industries.

MINE AND MAGNESITE AT CEDAR MOUNTAIN.

Western Magnesite Co.—The deposits of this Company are in the northeastern part of Santa Clara county near the boundary lines of Alameda and Stanislaus counties. The mine is connected to Livermore by a good road about 35 miles long with no heavy grades. The deposits have been operated from time to time for the past ten years and accredited with a considerable tonnage. The rock is exceptionally pure and white. The ore exposures are sufficient to warrant the assumption that the deposits are extensive. The equipment consists of two stack furnaces which are connected to the mine workings by a tramway about 2700 ft. long. Warehouse facilities have been provided, and living quarters, blacksmith-shop, and other accessory improvements made. For the past year or more the plant had been operated only in a small way, but recently resumed activity with a crew of 20 men, and has produced and shipped several hundred tons within the past three or four months.

Fresno Magnesite Co.—This deposit is conveniently situated, so far as its transportation facilities are concerned, being about one mile from the Santa Fe railroad terminal station Piedra, in Fresno county. The mine is reached by a road across the county bridge over the Kings river. The deposits are in the rather low, rolling, barren hills on the north side of this stream. The vein, where exposed, is said to vary in width from a few inches to about eight feet. It is reported that much of the ore contains rather high percentages of lime. The equipment, aside from the stack furnace, includes crushers, a steam plant, engines, dynamos, etc., and mine buildings. Most of the magnesite produced was sold to paper mills, but the plant has been idle for about two years.

Swindell Magnesite Co.—The presence of magnesite on the western arm of Cedar mountain, in Alameda county, has been known for some years, and development work has been done from time to time since 1905. The deposits, which are about 13 miles southeast of Livermore, were leased by the James H. Swindell Magnesite Co. in 1912 and construction of a furnace commenced, intended primarily to produce dead-burned magnesite for the steel mills. The mine is at an elevation of 3500 ft. above sea-level, and the roads leading to it have several heavy grades. The plant was operated but a short period this year, producing less than 100 tons during the trial run. Operations ceased owing to lack of sufficient capital. The extent of the deposit is not shown by the present development work. The

principal exposure is in a circular pit of about 30 ft. diameter and 25 ft. deep. The bottom of this pit is provided with a chute about 8 ft. deep, connecting with the tunnel below. Through this, which is about 75 ft. long, the ore is trammed to the crusher, where it is broken to pieces not exceeding two inches in length. The furnace is of the shelf or chamber type. When the crushed ore is delivered to the furnace, it passes first into the uppermost chamber, and when the furnace is in full operation a charge is kept on each hearth. When the calcination of the charge in the lowest chamber is completed it is discharged upon a floor of firebrick below the furnace, and is cooled, preparatory to sacking. The charge on the second hearth is then raked down to replace that just drawn, the charge of each of the upper hearths progressing downward by steps in this way.

Magnesco Refractories Products Co.—Practically the entire output of this Company has been consumed for plastic and insulating purposes. The deposits are situated near Winchester, a station on the Santa Fe branch railroad extending between Highgrove and San Jacinto in Riverside county. The deposit comprises a network of small veins for the most part, although one vein has been uncovered of considerable width. Much of the ore mined has required hand sorting, and the larger part of the material mined is thrown on the waste dumps. The plant of the Company, which is at Los Angeles, is not in operation at the present time, and it is reported that no further operations are planned at the mine.

Sonoma Magnesite Co.—A good deal of interest has been aroused lately in the statements which have appeared in the daily press with regard to extensive improvements of the magnesite deposits of the Company, about 8 miles north of Cazadero in Sonoma county. It is reported that construction work has been commenced on a spur leading toward the deposits, which are not as yet provided with calcining facilities. The Company plans production in a large way with the view of competing for business on the Atlantic seaboard. The Company will doubtless be able to secure a low freight rate to tidewater at San Francisco, whence it plans shipments *via* the Panama canal. Several veins of magnesite have been exposed, but the claims are not extensively developed.

Miscellaneous Activities

It is reported that some crude magnesite has recently been shipped from the vicinity of Cazadero and Cloverdale in Sonoma county, and from Coyote station, near Morgan Hill, in Santa Clara county. This ore has been calcined at the plant of the Pure Carbonic Gas Co. in Berkeley, the carbon dioxide content being recovered. Most of the calcined product is said to have been taken by an Oregon paper mill. In the foregoing, mention has been made of only those deposits that have been equipped for production or that will possibly become producers shortly. Deposits of this mineral are found

SWINDELL FURNACE USED AT CEDAR MOUNTAIN.

at many points in the Coast Range and in some places in the Sierra Nevadas. Some of these are apparently of considerable extent, and much of the ore is of excellent quality. *Bull.* 355 of the U. S. Geological Survey, entitled 'The Magnesite Deposits of California,' by Frank L. Hess, supplemented by *Bull.* 540-3, entitled 'Late Developments of Magnesite Deposits in California and Nevada,' by Hoyt S. Gale, will be found by those interested in making more careful investigation of this subject, to be excellent references and very complete.

Platinum is practically all recovered from placer deposits, mainly in Russia. It is now found in the Boss mine, Nevada, and the Rambler Copper & Platinum Co.'s property at Holmes, Wyoming. The mill was remodeled, and preparations were made to continue the operations through the winter. This mill in recent years has produced platinum concentrate, and the mine is one of the first in the world to contribute to the platinum production from lode deposits.

Cyanide imported into Canada in 1913 totaled 708 tons. In the first half of 1914 there was only 227 tons, or 38 tons per month, but in August this increased to 130 tons, due to mining companies getting in large stocks. No cyanide is made in the Dominion.

The Chisos mine at Terlingua, Texas, continued the important output of quicksilver maintained for many years, and was again in 1914 one of the largest producers in the country.

Stamp-Mill Test

By E. S. KING

*Stamp-milling has been receiving considerable attention during recent years, and several improvements and patent stamps have been placed on the market with some success. In view of the claims made for various types of mill, I decided to make a test between two of them. The plant was erected at Tincroft, which has the distinction of possessing one of the oldest reduction works in Cornwall. Accordingly, two Nissen single-stamp mills were obtained, also a Sandycroft (English make) five-head ordinary mill. These two units started crushing in June 1914, and the figures of the comparative test are now available. Each Nissen stamp weighed 2000 lb., while the five others each weighed 1250 lb. The two batteries were driven by independent motors, the consumption of power being carefully checked and tabulated by the Cornwall Power Co. Only the coarse material that passed over the grizzly was sent to the breakers feeding the mills, the fine being diverted to the old Cornish battery for treatment. Both mills, of course, would have shown higher capacities had the fine been included. In each case, the screen was of 10-mesh standard.

Result of test from June 18 to July 16, 1914, showed the following:

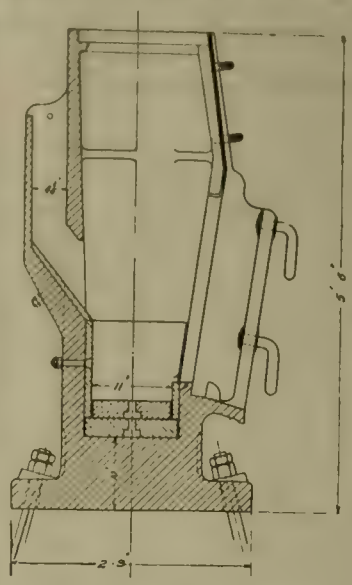
	Ordinary.	Nissen.
Ore crushed, tons	854.44	562.03
Total run, days	23.89	24.61
Duty per day, tons	35.765	22.837
Stamp duty each, tons	7.153	11.418
Total horse-power consumed	16.231	12.176
Horse-power per ton crushed per hour	10.959	12.796
Tons per horse-power per day	2.19	1.875
Cost of power, cents per ton	10.638	12.422

The average grading analysis of the product was as follows:

Mesh.	Ordinary, per cent.	Nissen, per cent.
+ 20	13.37	15.63
+ 30	15.61	15.97
+ 40	9.21	8.30
+ 60	12.08	11.88
+ 100	10.55	9.94
+ 150	9.43	8.13
+ 200	3.03	3.20
— 200	26.40	26.63
	99.68	99.68

These figures do not show any great difference in the grade of the pulp from the two mills. The duration of the trial being under a month, the cost of maintenance could not be estimated accurately.

The five-head mortar-box was specially designed by myself in accordance with previous experience in Western Australia. The box was of the straight-backed type with detachable front, rounded corners (to strengthen), cast-steel liners standing 12 in. above the dies and bolted in position with countersunk headed bolts. The high crushing capacity is mainly due to the small area between the shoes and the box, this being only one inch and insures a quick return of the uncrushed pulp to the dies. The screen was made to fit so that the bottom was flush with the inside liner. This was done by putting a filling piece at the bottom of the screen-frame, with the sides tapering to nothing at the top. The object is twofold: (1) it puts the screen nearer to the stamps, and stops any clogging on the inside lip of the box; (2) it gives a greater angle to the screen, thus allowing for a quicker discharge of sand than if the screen were vertical.



SECTION OF MORTOR-BOX DESCRIBED.

The stems used were of 4 in. diameter, and were shorter than usual by 4 to 5 feet, and this, I would point out, reduced the vibration and friction to a minimum. The order of the drop was 1, 3, 5, 2, 4.

The success of an ordinary stamp-battery, I contend, is due principally to having a properly designed mortar-box, the stamps falling exactly on the dies well under the cam-shaft. This cannot be secured, unless there are strong iron guides (same as were used in this test), and dies made to fit the box.

Many mill-men make the mistake of having the base of the dies too small, and putting pieces of iron between them to keep them in position. This is bad practice, for in the event of one piece of iron getting dislodged, it throws the whole of the dies out of place, thereby at once reducing the crushing surface and efficiency. Hitherto, the necessary space for inside gold and silver amalgamation had generally somewhat influenced the standard design of the usual mortar-box; but in this case, in view of obtaining the greatest capacity, it was entirely disregarded.

In Western Australia, the use of cyanide in place of amalgamation brought about this welcome improvement, and the old boxes packed with hardwood and steel plates gave the following capacities, equal to an increase of over 50% on previous results:

Screen, mesh.	Weight of stamps, pounds.	Duty, tons.
30	1050	4.76
20	1050	6.27
10	1050	8.90

These results were obtained on ore containing 50 to 60% granite, therefore on clean quartz, it can be assumed, a much better duty would have been obtained.

*Abstract from *The Mining Magazine*, December 1914.

DISCUSSION

Readers of the Mining and Scientific Press *are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.*

Amalgamation in Hardinge Mills

The Editor:

Sir:—There being a difference in the results obtained in two mills by amalgamation, both Hardinge, I would like an explanation of this difference. Mr. Caetani, in his article, 'The Design of the Plymouth Mill' (the *Press*, October 31, 1914), states, in his discussion of amalgamation, that when amalgamation inside the Hardinge mill was employed "It was found that if the amalgam was kept sufficiently soft it would build up on the pebble lining, filling up the depressions of the mortar between the pebbles. It was hopefully expected to find large amalgam balls rolling around with the pebbles, but this was not found to be the case; at the bottom of the mill there was a slough of amalgam, sand, and metallic iron, which in rolling, caused the coarse gold to amalgamate and, as the amalgam was formed, it became plastered upon the lining. Whenever the feeding of quicksilver was stopped, the amalgam would dry up, crumble, and be thrown out of the discharge opening of the Hardinge, where it would build up in thick layers. * * * Inside amalgamation has now been discontinued, solely for the reason that the quicksilver losses were enormous, due to the flouring inside the mill." R. B. T. Kiliani, in his article, 'The Incaoro Mill, Bolivia' (the *Press*, November 21, 1914), says, in regard to amalgamation in Hardinge mills: "Mercury is fed in at the head end of the ball-mill, amalgamated in this machine, and passes through to the pebble mill, which catches the greater portion of the coarse gold. The machines are shut down once a day to make a clean-up of the amalgam in the mills, from which approximately 75% of the total recovery is made. The amalgam in these machines is very hard, containing slightly over 50% gold. This is attributed to the fact that the pounding of the balls and pebbles in the mills squeezes out all the free mercury, leaving a hard amalgam, which balls up and tumbles around." Will Mr. Caetani and Mr. Kiliani kindly explain these different actions and results? At the Incaoro mill, hard balls of amalgam formed; at the Plymouth they did not, though expected; the amalgam being ejected from the mill if allowed to become hard by ceasing to feed quicksilver. Mr. Caetani says soft amalgam would cling to the mill lining, the surplus quicksilver forming a pool of thin amalgam in the bottom. Mr. Kiliani says the surplus quicksilver is squeezed out and hard balls formed, but does not say what becomes of the excess, nor does he mention any soft amalgam as clinging to the lining. Why should hard balls form in one case and not in the other? I judge the difference to be due to the different amounts of quicksilver fed, one millman probably feeding more in proportion to the amount of gold present than did the other. Had Mr. Caetani fed less quicksilver, he would have obtained hard amalgam, though it might not have remained in the mill and formed balls. Of course when no quicksilver was added the amalgam became very hard, crumbled, and was ejected. As the interior of the mill is not visible, the operator probably would have difficulty in determining the proper amount of quicksilver to add to secure and maintain the desired consistence of amalgam. I do not think there could be any surplus quicksilver at the Incaoro mill, only enough being added to form a hard amalgam. At the Plymouth mill the amalgam was pasty and all the coarse gold ground fine so that the amalgam contained only 22% bullion. At the Incaoro, 50% of the amalgam was gold, the difference probably being due to grinding of the gold being prevented by the hardness of the amalgam.

At the Plymouth mill a large amount of quicksilver was floured, but Mr. Kiliani does not mention floured quicksilver, so we must suppose that an objectionable quantity was not formed. Why the difference? Is it due to the character of the ores? The Plymouth ore consists of quartz, slate, pyrite, and arsenopyrite. The concentrate forms 1.8% of the ore, a large percentage of it being arsenopyrite. In the article, 'The Incaoro Gold Mine and Mill' (the *Press*, April 4, 1914), F. C. Lincoln states in regard to the ore: "The principal vein mineral is quartz, always accompanied by some white mica and native gold, and occasionally also by arsenopyrite, pyrrhotite, and pyrite. * * * The arsenopyrite and pyrite * * * are present in such small quantities as to be relatively unimportant." The country rock is described as being a "black non-fossiliferous slate." The only difference in the ores seems to be the greater proportion of sulphides in that at the Plymouth, but perhaps there is a difference in the character of the slate, some of which necessarily goes to the mills. The motion of the pebbles would tend to produce the same amount of flouring in both cases if all conditions were the same, but as the amalgam at the Incaoro was kept harder than that at the Plymouth, I judge there would be a smaller percentage of quicksilver floured and not a sufficient amount to make its loss important.

Perhaps there is nothing in the Incaoro ore to cause 'sickening' of the quicksilver, and hence the globules formed by the pebbles readily unite. The respective

amounts of arsenopyrite present may account for the difference in the quantities of quicksilver floured, there being almost none at the Incaoro and an appreciable amount at the Plymouth. There may be a difference in the slate that has an influence on the flouring, that at the Plymouth contains graphite, and perhaps that at the Incaoro does not, which may account for some of the differences in flouring. I do not know that graphite will 'sicken' quicksilver, but it may in the finely divided condition in which it occurs in the slate of the Mother Lode. I know that the dirt that is acquired during a day spent in a Mother Lode mine cannot be washed from the hands as can ordinary mud or dust, but that, like grease, soap is required to remove it. Perhaps it clings to the surface of a globule of quicksilver as tenaciously. Perhaps if Mr. Caetani and Mr. Kiliani would give more details of the methods employed at the two mills the differences in results could be readily explained.

Aside from the above, please ask Mr. Caetani to describe the amalgamating device that he states is to be attached to the Hardinge mill at the Plymouth and tell what results are obtained. Also ask Mr. Kiliani to describe the method of cleaning-up the ball and the pebble-mills at the Incaoro.

F. J. Girard.

Dedrick, California, December 28, 1914.

[With great pleasure we send these inquiries on to Mr. Caetani, who happens to be now in Italy, and Mr. Kiliani, who is in Bolivia. This interesting discussion of their papers by Mr. Girard, in California, emphasizes the world wide brotherhood of technical men, at the same time that the circumstance excuses delay in reply. In the meantime Mr. von Bernewitz is good enough to suggest possible answers to the questions, based upon experience in New Zealand and Australia. Who else has a suggestion?—Editor.]

The Editor:

Sir—Mr. Girard's discussion of the peculiarities of amalgamation in Hardinge and other mills raises some interesting points, which seem quite as difficult of explanation as they are interesting. There seems to be little difference in the ores treated at the Plymouth and Incaoro mills, although the gold may be finer in the former than in the latter. Any large difference in the pebble load would also affect amalgamation, and possibly the speed. Graphite in the slate mixed with the ore forms a greasy scum when crushed, and most likely would tend to 'sicken' the quicksilver, although I did not hear on the Mother Lode that it affected plate amalgamation. It may be argued that amalgamation in a mortar-box is subjected to great scouring action, when the stamps splash the pulp violently against the inside, yet when properly done there is little loss from flouring at this point. Apart from recovery of gold in the box, a steady flow of pulp over copper plates is about the best medium in amalgamation. Candidly, I would not try amalgamation in a Hardinge, tube, or ball-mill, in which the action of grinding is violent, and where little else than flouring of the mercury could be expected.

The effect of graphite in cyanidation is still a matter of dispute, some metallurgists being convinced that it does precipitate gold from solutions, while others say it does not and whatever precipitating is done is by occluded gas in the graphite. However, this is another discussion.

I never had much use for any amalgamating device, preferring to stick to the old methods. The theory advanced by inventors of amalgamating machines is generally to have better contact between the gold in pulp and mercury, therefore they try to force the pulp through, or on to, a mix with it. Flouring often results from this treatment. Electro-amalgamators work on the principle of keeping wells of quicksilver in an active condition, thereby inducing amalgamation.

Grinding pans are extensively used in Australia and in New Zealand, and with them amalgamation. The action in these is violent enough, but mercury losses are always low. The only system of amalgamation in tube-mills that I think well of is that used in the high-grade mills of the Nipissing and Buffalo mines at Cobalt. But that is another matter, as it involves the treatment of a few tons of 2000 to 3000-oz. silver ore with a strong cyanide solution, and a greater weight of quicksilver than there is ore in the mill. The process is satisfactory, but mercury losses are admitted to be high, and steps are being taken to recover the metal. The different results obtained at the Plymouth and Incaoro mills bears out what I often say, that what applies in one plant is not necessarily successful in another, even with similar ores, and no hard and fast rule can be laid down. Peculiar results occur, and often they are not always explainable.

M. W. von Bernewitz.

San Francisco, January 9.

Valuing Placer Ground

The Editor:

Sir—In regard to the correspondence in your paper upon the above topic, your contributors are in agreement in one respect—that calculations shall be based upon the assignment to each borehole of a definite superficial area. It is over the relative claims of an 'outside,' an 'inside,' or a 'corner' hole that they are at variance. There is also a tendency to regard the matter as exclusively one of values and to lose sight of the secondary element of capacity. In dealing with 'units' and 'half units,' or the values at opposite ends of a single diameter, as is advocated by Mr. Jennings, it is well to remember that the engineer might be making calculations for a large and irregular field instead of the restricted area given in the example.

In the following attempt I have assumed that the solid body of the deposit has been tested in five vertical sections; and on the assumption that the untested is also the unknown, and that the average is accepted as the best guess that can be made at the probable. I have

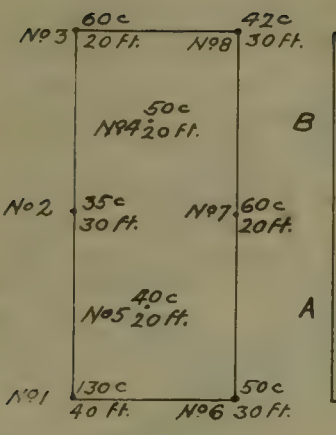


Diagram 1.

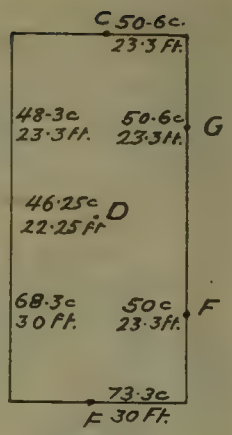

Diagram 2.

supplied the missing values by an average of all the nearest equidistant boreholes. The first diagram represents the ground as tested, the second the calculated averages required to complete the data for each section.

The results may be tabulated thus:

Averages

Avg. of holes.

Point A—2, 5, 1 = $\frac{35 + 40 + 130}{3} \times \frac{30 + 20 + 40}{3} = 68.3 \times 30$

Point B—3, 4, 2 = $\frac{60 + 50 + 35}{3} \times \frac{20 + 20 + 30}{3} = 48.3 \times 23.3$

Point C—3, 4, 8 = $\frac{60 + 50 + 42}{3} \times \frac{20 + 20 + 30}{3} = 50.6 \times 23.3$

Point D—5, 2, 4, 7 = $\frac{40 + 35 + 50 + 60}{4} \times \frac{20 + 30 + 20 + 20}{4}$ 46.25×22.25

Point E—1, 5, 6 = $\frac{130 + 40 + 50}{3} \times \frac{40 + 20 + 30}{3} = 73.3 \times 30$

Point F—6, 5, 7 = $\frac{50 + 40 + 60}{3} \times \frac{30 + 20 + 20}{3} = 50 \times 23.3$

Point G—7, 4, 8 = $\frac{42 + 50 + 60}{3} \times \frac{30 + 20 + 20}{3} = 50.6 \times 23.3$

Inserting these values we obtain:

(At unit distance apart)

Sections 3 C 8 = $\frac{60 + 50.6 + 42}{3} \times \frac{20 + 23.3 + 30}{3} = 50.86 \times 24.43 = 1242.5$

B 4 G = $\frac{48.3 + 50 + 50.6}{3} \times \frac{22.3 + 20 + 23.3}{3} = 49.63 \times 22.2 = 1101.8$

2 D 7 = $\frac{35 + 46.25 + 60}{3} \times \frac{30 + 22.25 + 20}{3} = 47.08 \times 24.08 = 1133.7$

A 5 F = $\frac{68.3 + 40 + 50}{3} \times \frac{30 + 20 + 23.3}{3} = 52.76 \times 24.43 = 1289$

1 E 6 = $\frac{130 + 73.3 + 50}{3} \times \frac{40 + 30 + 30}{3} = 84.43 \times 33.3 = 2811$

128.44 7578

$\frac{7578}{128.44} = 59c.$ Average depth 25.7 ft.

This value may seem to be higher than that obtained by some methods, but the quest for a system is governed by accuracy and adaptability rather than conservatism. It is obvious that the desirability or otherwise of using calculated averages and the selection of the elements of these guesses at the truth are matters determined on any field by the placing of the borings.

Edmund Bonella.

London, October 26, 1914.

Precision of Thought

The Editor:

Sir—Mr. Prosser's letter in your issue of December 5 vehemently criticizing the use of the singular form of the verb in your statement "• • • 600,000 tons was crushed," quotes "a fundamental rule of grammar, 'plural noun, plural verb'," and, further on, excoriates grammar as the worst of "the various kinds of trash" taught in our schools. Why anyone who holds grammar in such contempt should attempt to insist that his construction is the correct one is not clear, but the correctness of your use of the verb is beyond question.

The subject under discussion was *ore*, and there is nothing plural about ore except in the case of a mine which produces more than one kind, as the Shattuck Arizona does. The ore *was crushed* to the amount of 600,000 tons. The tons mentioned measured the quantity of ore, but they were not crushed into pounds or ounces. Mills crush ore, not tons, and doubtless this plant was designed for that purpose. The only occasion that I think of where the tonnage itself is "crushed" is when a capable engineer examines a mine in which the amount of ore has been overestimated.

J. Nelson Nevins.

Los Angeles, December 10, 1914.

The Hardening of Metals

At the 74th meeting of the Faraday Society in London, on November 23, the above was the subject of a general discussion. The chairman was Sir Robert Hadfield of steel fame. Referring to the history of the most important hardened metal in the world, namely steel, he said that the world's future progress literally depended upon understanding correctly and in a scientific manner the hardening of metals. The accurate determination of the hardness of steel alloys was now being investigated by a special research committee of the Institution of Mechanical Engineers. Having referred with deep regret to the great loss sustained by the science of metallurgy in the death of Dr. Martens, in whose honor Osmond had invented the metallographic term 'martensite,' he concluded by showing a specimen, probably the first to be exhibited in modern times, of an ancient piece of high carbon steel which had been hardened by quenching. It was taken from beneath the stone pillar of Heliodorus at Besnagar, India, and it contained 99.2% Fe, 0.70% C, 0.04% Si, 0.008% S, 0.20% P, 0.02% Mn, and traces of nickel and chromium. This specimen, perhaps more than 2000 years old, was the first example of ancient steel which he knew of that contained sufficient carbon to be called steel.

CONCENTRATES

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

GOLD AND SILVER producing mines in the United States and Alaska, but not including several silver-producing copper mines in Michigan, any zinc mines in the eastern and central states, a few in the far West, or lead mines in the central states, totaled 5276 in 1913. These consisted of 1774 placer and 3502 deep mines. The figures in 1912 were 2044 and 3567 respectively.

THE INDUSTRY OF THE COAL-TAR DYES was the subject of an address delivered before the board of directors of the General Chemical Co., New York, on October 23, by Bernhard C. Hesse. The full paper appears in the December issue of *The Journal of Industrial and Engineering Chemistry*. The industry yields no less than 1200 different products, includes as many or more processes of manufacture, and requires many hundred different sets of apparatus of varying capacities; therefore the complexity of the manufacture is evident. These 1200 products are made from 10 products obtained from coal-tar by distillation, refrigeration, expression, or the like.

A DOUBLE-DECK AMALGAMATING TABLE has been devised by E. V. Davies of Folsom, California, and tried by him in a mill in Plumas county. The upper or movable table can be set at a position just under the lip plate, a little ahead or behind the discharge point of same, to take any amount of the total pulp flow. The table could set or rest on the stationary table when in working position and be arranged to be raised or rolled away from it when necessary, or hung by rods from the building above. A short length of such an upper table was tried with good results in amalgamating float gold. It was set in a position with the lip plate to catch only the lighter pulp; bringing it more to rest on this table and in better contact with the mercury than could be done if carried down with all the pulp. Such a table will divide the pulp, and more water may be used in the battery, resulting in a more rapid discharge with less slime and an increased stamp-duty, and it may be of use where floor space is limited.

THE WATSON-DENNY GRINDING PAN is used in certain mining districts of New Zealand with satisfactory results. It is somewhat similar to the pan as used at Kalgoorlie, but the shoes and dies are cast with small corrugations, so as to afford a greater grinding surface than the plain ones. The overflow is discharged through a number of 1-in. holes at the top of one side of the pan into a lip attached. At the bottom of this lip is a hole through which the coarser material is returned to the pan to be further ground. In front of the discharge holes is a board placed to check the flow and aid the heavy sand to sink. According to D. B. Laurie, who operated these pans on the Thames goldfield, six of them ground 50 tons per 24 hours, the clean sand feed being 25 mesh, with no slime, and the discharge passing a 100-mesh screen. When fed too fast the surface of the pulp in the pan was 'dead', and the overflow lip contained a quantity of sand. These pans are 5 ft. diameter, and are gear driven.

THE DEEP LEADS, or gravel channels, of Victoria, have produced a great deal of gold in the past, but this form of mining is very quiet now. Water has always been a detriment to economical work. The system is to sink a shaft to bedrock, drive under the 'wash' and then put

A DRAINAGE BORE IN A VICTORIAN DEEP-LEAD MINE. NUMBERS OF THESE ARE PUT UP TO THE GRAVEL FROM WHICH COMES THE HIGH PRESSURE SHOWN. THE SCREW-JACK IS USED FOR FORCING UP THE TUBING. MINERS AT FACE 20 FT. BEYOND.

up boreholes to drain it. The Langi Logan company, in the Ararat district, has been pumping for three years, and has reduced the pressure of the water in the ground from 145 to 14 lb. per square inch. Pumps used are one 20 and one 22-in. lift, with 9-ft. stroke. Another pair of 18-in. lifts have recently been started also. The gold in the gravel is shotty, the deepest being at 350 ft. The accompanying picture shows the flow of water from the Loddon Valley Goldfields property, another deep lead scheme.

MINING IN THE FAR NORTH*

The Present Outlook for Quartz Mining in the Fairbanks District

By EMIL EDWARD HURJA

Lode mining is a comparatively new industry in the Fairbanks district. The first quartz claim in the district was located by John C. Rose on Chatham creek on August 28, 1903. It was known as the Blue Bell lode. The next year saw several more claims staked, but real lode development did not start until the Rhoads-Hall property, consisting of the Free Gold claim on Bedrock creek, was opened in 1908-9. Then many claims were staked, and whole hillsides were blanketed with locations. As many of the locations were not followed by active prospecting or development work, the lode-mining industry did not fare beyond the nursing bottle stage.

In the last few years Fairbanks has experienced some real healthy development, although in 1913 and 1914 the growth has been less than in the two years preceding. Many mistakes have been made, ore has not been sampled carefully, mills have been placed without careful enough investigation of conditions, and expensive equipment has been installed without sufficient ore in sight to justify reduction plants, but progress has none the less been substantial.

The development of lode mining in the Fairbanks district came with the depletion of the richer placer deposits of the creek bottoms. Previous to 1911 about $60,000 was taken out; in 1911, the production was $64,100; in 1912, $200,000; in 1913, $175,000; and in 1914, about $250,000 or $300,000. In 1912 there were six mills in operation; in 1914, five operated, three of them at intervals only. The reason assigned is the fact that many of the mills were installed before sufficient underground development had been done. Water conditions often have caused some of the mills to close down, especially during the winter time. It is only by drilling that a permanent water supply has been obtained at some of the claims. Most of the properties of the district have been opened up with local capital and by local men, and the mistakes made in the mining have been due largely to inexperience and lack of knowledge as to quartz mining.

Gold-bearing quartz has been found in the Fairbanks district in many widely scattered areas. The main belt appears to be centred in the region between the Cleary and Fairbanks creek watersheds. Most of the prospects occur along the headwater tributaries of Cleary and Fairbanks creeks, although some very promising properties have been developed along Twin and Pedro creeks, on Fox gulch, a Goldstream tributary, on Dome and Little Eldorado creeks, tributaries of the Chatanika river. Then there is another belt surrounding the Ester Dome region, where quartz has been found on Eva, Ready Bullion, and Sheep creeks.

There are a number of locations on Fairbanks creek. The easternmost prospect is the Charles claim, near the head of Walnut creek. An 18-in. vein has been found on the claim, but development is at a standstill. On Moose creek, Crites & Feldman have done considerable prospecting on their holdings between that stream and Too Much Gold creek. Two veins have been uncovered and traced for a distance of about 1500 ft., ranging in width from one to four feet. During the summer of 1914, a reduction plant, consisting of a five-stamp Hendy battery, was moved from the Pioneer Mining Co.'s millsite on lower Chatham creek to a new millsite on Moose creek, below the tunnel site of Crites & Feldman. The mill started crushing in September.

At the head of Too Much Gold creek, the Anderson, Nars & Gibbs property is being developed slowly by Gibbs, who has purchased the interests of the other two. The Cook holdings, near the mouth of Too Much Gold creek, and consisting of the Governor, Plumbum, Excelsior, and other claims, have been idle during the past year, because the owners stampeded to the Chisana. On the Mizpah claim, owned by A. Hess and Charles Thompson, considerable work has been done. A resumption of sinking was planned for the fall of 1914. Joe Connors and Bert Stevens are prospecting the Ohio group of claims, opposite No. 13 and No. 14 Above, left limit, placer claims. They have an 80-ft. shaft on a vein averaging 2½ ft. in width, and have 20 tons of ore on the dump. On the Mayflower claim, a 50-ft. shaft has been sunk and driving is being continued along the vein at that level. The vein is 20 in. wide. A shipment of 7½ tons was milled in May 1914 and gave returns of $60 per ton. Kellen and Vanarsdal are prospecting the Thanksgiving claim, below the Connors-Stevens prospect. A shaft is down 36 feet.

Farther upstream, Chris Foss and Louis Fairvain have taken a lease on the American Eagle quartz claim and have started prospecting it. The claim has but recently been released from litigation which lasted for three years. L. J. McCarthy, an old-time prospector of the district, who has a number of claims on the divide between Fairbanks and Wolf creeks, recently took a lease on the Pioneer claim, owned by Clark, McGowan, McDougall, and associates. In July 1914, 32 tons was milled, having a value of $2200. An incline shaft is down 160 ft., and adits have been driven 80 ft. each way on the vein. On the 50-ft. level, 80 ft. of adits has been driven. The most recent work has been done at the 50-ft. level. The vein is highly mineralized and is from 7 to 8 in. wide. A cross-stringer 7 in. wide was found recently, and attention will be devoted to it soon.

The Pearl Creek valley, tributary to Fish creek, has several prospects, the most promising of which are owned by Murphy & Perrault and Mike Steipovich.

On Wolf creek are a number of claims which have been worked during recent years. The Homestake tunnel site, owned by the Homestake Mining Co., is under lease to George Nightingale. The main adit has a length of 750 ft., in which it cuts ten different stringers. One of these is being worked, the drift along the stringer starting 315 ft. from the portal of the main adit and running northeastward. The tunnel has been driven 300 ft. Stoping of the five-inch vein has yield-

Co.,' November 14; 'The Klondike, the Treadgold Placers, and Outlying Districts,' November 28; 'The Upper Yukon: Circle City, Eagle, and Woodchopper,' December 5; 'Placer Mining in the Fairbanks District,' December 19 and January 2.—EDITOR.]

ed wonderfully rich ore. Thirty-three tons was milled in November 1913, with an average value of $170.59 per ton. In July 1913, 28 tons was milled with an average value of $109. Twenty-five tons was on the dump in September ready for shipment down the creek to the Rexall mill. On the Rexall claim, adjoining the Homestake on the downstream end a two-stamp Hendy mill, operated by a gasoline engine, was erected in 1912. The installation of the equipment was not made wisely, as the stringer which was being worked suddenly pinched out. Still, a new lease on life has been taken at the Rexall, with the granting of a lease a few months ago to Fred Crouch and associates. Their lease has a term of ten years, with a 10% owners' royalty on all ore milled. The vein on which they plan to work has a width of four to seven feet. Operation of the mill costs $9.50 for fuel each 24 hours, a great saving over steam boilers in use at other mills in the district.

In the Chatham Creek valley, work has been temporarily suspended on the Chatham Mining Co. and Pioneer Mining Co. properties because of the high cost of supplies and labor. E. L. Scrafford is in New York attempting to float a company to take over the Chatham property. The claims have considerable work done on them; the mill on the property, two 2-stamp Hendy batteries, is idle at present, although it has produced several hundred thousand dollars. The pioneer holdings include the first lode location of the district, the Blue Bell claim. The Jupiter-Mars and Quenboe properties are on the ridge between Chatham and Wolf creeks. No work is being done on them now.

Perhaps the best property in the district is the Free Gold claim, owned by L. B. Rhoads and W. C. Hall. The claim was located in 1908 and from the first it paid development costs. Rich ore was found near the surface and the first returns came from ore which was crushed with mortar and pestle and then panned for the free gold. Later small shipments were sent to a 3-stamp customs mill which had been erected at Fairbanks. In 1911 shipments to a 10-stamp mill at Chena, 12 miles below Fairbanks, were made. One hundred forty-seven tons yielded $17,645, or an average of $120 per ton. Mining is done from a main adit with a length of about 1200 ft. An intermediate adit 140 ft. farther up and a third one, the Penrose, 50 ft. higher, together with smaller adits, bring the total on the claim to over 5000 ft. A winze has been sunk to a depth of over 100 ft. The 70-ft. level has been developed a distance of 872 ft. and the 100-ft. level a distance of 890 ft. along the vein. The adits drain the workings, the water being flumed to furnish the mill supply. A 2-in. Buffalo pump operated by a 7-hp. General Electric Co. motor keeps the winze workings free of water. Hendy cars—1600 lb.—are used to tram the ore to the mill, which is situated several hundred feet below the mouth of the main adit. The ore is crushed with a 7 by 9 Blake crusher, fed to the single battery of five 1000-lb. Hendy stamps with an automatic feeder, and the pulp discharged through a 40-mesh screen directly to the plates. The stamps approximate 100 drops per minute, with a 5-in. drop. The plates are 16 ft. long and 4½ ft. wide. No vanner is used, as over 90% of the gold is recovered in the mortar box and on the plates. The mill has a capacity of 17 tons each 24-hr. day, or an average of above 400 tons per month. The chrome steel shoes are replaced every four months; the dies every three months. A 50-hp. battery of boilers operates two American Blower engines, one of which operates the mill and the other a General Electric Co. motor and lighting plant. A Hendy clean-up barrel is included in the mill equipment. The 1913 output of the mine has not been made public, but 48,000 sq. ft. of vein matter was worked, the vein having a width of from a few inches to 3 ft. 4 inches.

There is some small-scale mining being conducted on the claims of the Tanana Quartz & Hydraulic Mining Co., situated on the ridge between Bedrock and Chatham creeks. The discoverer of the claims was Antone Goessman. The Tolovana property, which has a 2-stamp Nissen mill and a small Huntington in connection, is on Willow creek. The claims in the group stretch between Bedrock and Willow creeks. Work at the Tolovana has been suspended indefinitely because of financial difficulties. The Emma claim at the head of Willow creek is being worked by I. Overgaard. The Newsboy claim at the extreme head of Cleary creek, on the ridge between it and Little Eldorado creek, has about as much work done on it as any claim in the district, but because the ore did not average above $15 to $20 per ton, the plant was forced to suspend operations. A five-stamp Hendy mill is situated one-half mile below the shaft.

The north slope of Dome creek is almost entirely covered with the holdings of the Reliance Mining Co. There is a 2-stamp Nissen mill on the creek, immediately below the claims, but it was not operated much during the past year. Some very rich ore has been found on this claim. A one-half interest in a year's lease on the property sold in 1912 for $30,000.

The Friedrich property on Vault creek is idle, as are several other prospects on smaller tributaries of Vault. At the head of Sheep creek, tributary to lower Goldstream and heading into Ester dome, the discovery in 1912 of a boulder literally plastered with free gold led to a revival of prospecting there. Nothing of great importance has been found, however.

The Rainbow mine is the principal property in the Twin Creek valley, although Martin Harrais and others are working on the Moonshine and Sunshine claims nearby, with hopes of ultimate success. The Rainbow shaft is 131 ft. deep. At the 100-ft. depth, 209 ft. of drift has been driven west and 135 ft. east on the vein. Five hundred tons of ore has been stoped from the vein. The failure of a Straub mill which was erected two years ago but did not operate successfully has delayed development of the property. L. M. Drury recently took a lease on the claim and plans to continue the development work on a big scale. A 25-hp. Lidgerwood hoist, with 50-hp. boilers, blacksmith-shop, and buildings are on the claim. Because of the non-fulfillment of option and lease provisions, the claim had reverted to the original discoverers, Herchberger & Zimmerman.

In the Ester district, the Tyndall & Finn discoveries on St. Patrick creek are said to be the most important. They were made early in the year. The Hudson brothers made good finds on Ready Bullion creek, in the same vicinity, in 1911, and after a little development they erected an expensive milling plant, made up of two Nissen stamps, concentrating tables, and a mill building considered the best in the interior. The mill operated only a short time when it became evident that there was not enough ore to justify continuous operation.

Another property which is considered of importance to the Fairbanks district is the Dempsey-Linden property on Sourdough creek, a tributary of the upper Chatanika waters. It is being developed each winter. Other districts in which quartz mining is carried on are the Kantishna, the Big Chena, and Tenderfoot districts. Considerable lode gold mining also is carried on in the Chandlar district, north of the Arctic Circle. There are a few silver-lead properties in the Koyukuk. The general future of quartz mining in the district depends on a general reduction in mining costs. Fuel costs are too high, and, until cheap power is obtainable, there can be no real healthy general development. This seems to be assured with the probable construction of the government railroad through the Nenana coalfields. Then there is the factor of wages. A general reduction of living costs in the district would tend to reduce wages to the point where many properties which have orebodies proved up on them could be worked with profit.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

NEW YORK

THE COPPER SITUATION.—BRADEN MINE AND MILL.—CHUQUICAMATA PROGRESS.—INTERNATIONAL NICKEL CO. AND EXPORTS TO GERMANY.—BARTON SEWELL.

Last week showed a marked improvement in the market for copper. December sales had been lower than November, and the year opened with a rather gloomy outlook. Whether because it appeared that England would make a conciliatory reply to the American note in regard to the detention of shipments, or for whatever reason, there was a marked improvement in the buying during the first week of the new year, and at the end of the week there were signs that there would again be an upward movement in price. Exports for the preceding week had been about 12,000,000 lb., more than half of it consigned to France and most of the rest to England. Early in the week T. J. Walsh, senator from Montana, made quite an important speech in the Senate in dealing with the question of interference with American ships by British cruisers, and especially referring to copper shipments. He said: "The exigencies of the war, in which we are in no wise concerned, will necessarily entail hardship and suffering on the laborers in the copper mines and in industries more or less dependent upon them. It may reasonably be assumed that the government of Great Britain, with which we happily are in amity, would not wantonly add to the detriment which is occasioned by the destruction of the German market the discomfiture and distress that must ensue from the closing to our trade of the ports of the neutral nations of the Continent."

The estimated figures for the output of copper last year compiled by the U. S. Geological Survey have been given out and show a decrease of 8½% as compared with 1913. The latter year showed a small decrease as compared with 1912, so that the 1914 figures of 1,129,000,000 lb. are quite a little smaller than those of two years ago. As most of this decrease is due to the voluntary reduction of output by the various producers, it is probably uniformly distributed, and is not confined to any particular group of states. Utah, however, will show about the same output as last year, because up to the time the reduction in output was made it had been turning out considerably more copper than the year before.

The Braden is making an improved showing lately. It will be remembered that while the amount of ore reserves estimated in the first report on the property have been greatly exceeded, working costs have also been greater. This is a cause for congratulation rather than the reverse, because while the ore reserves are fixed, there is a good possibility that the cost can be reduced, and indeed good progress has been made toward reducing them. The total ore reserves are now estimated at 108,000,000 tons containing 2.5% copper, and the somewhat unfavorable showing which the mine has been making so far has been in part due to the fact that it has been operating on material which is considerably lower in grade than the average. The average material treated in November was 2.18% copper, and this was the highest of all recent months. However, the reduction in November was not so good as in October, when the new mill made a recovery of 77.7% and the Minerals Separation plant made a recovery of 76.95%, a net total of over 81%. The net total recovery in value was 73.9%. During the first half of December the total was 76.5%. The plant could produce much more than it is producing at present, but it is being held down in order to correspond with the reduction in output which is being made at the mines in the United States. The plant has been running for some time, and the leaching process has also been in operation and has shown a recovery so far of 93.3%. The usual delays and difficulties in starting a new plant like this have not failed to appear, and the electrolytic equipment for the recovery of copper from the leaching solution was started at the end of December. Probably results from this will not be available for some time until it gets in regular working order. Working costs have already been reduced to 7.5c. per pound, and Pope Yeatman is of the opinion that there is a good possibility of eventually reducing the cost to 6.5 cents.

Good progress is also being made at Chuquicamata. Both the metallurgical and mining plants are practically completed. The work on the power plant has been delayed because the machinery was being supplied from Germany, but the steamer carrying the last of it had safely sailed from Germany before the war started, and the Company hopes that before long it will be safely landed in Chile. The expectations of the management are that the plant will be in operation by April 1. E. A. C. Smith is leaving for Chile at the end of this month, and will be on the ground to supervise the starting of the plant which he has designed.

ELECTROLYTIC TANK HOUSE, CHUQUICAMATA, CHILE.

The International Nickel Co. has declared its regular quarterly dividend of 1½% on its preferred stock, payable February 1. No action will be taken on the common stock until next month. The Canadian government has issued a memorandum in regard to the affairs of the International Nickel Co., and the question of exports of nickel to Germany. The Company has allowed free access to its books to representatives of the government, and all exports have been investigated so that it can be certain that no nickel has gone through to Germany or Austria. The alarm which the Cana-

dians have exhibited over the possibility is rather exaggerated, because the nickel mines in Norway which produced several million pounds last year could easily supply the demands of Germany and there would be no need to depend once on the Canadian nickel. In attempting to take any vigorous action, the Canadians are more likely to injure themselves than anybody else, since nickel production is an important industry in Ontario.

All the plants and offices of the American Smelting & Refining Co. stopped work for an hour at 11 o'clock last Saturday, when the funeral of Barton Sewell, vice-president of the organization, was held. He was a quiet man and was so much overshadowed by the publicity which the Guggenheim Bros. receive that few people nowadays realize that he had much more to do with the formation of the Company than they had, since he put through the various consolidations which led up to the formation of the American Smelting Co., in which he was the chief factor and which became the nucleus for the A. S. & R. Company.

WASHINGTON, D. C.

BILL TO REGULATE AREA OF COAL LANDS CONTROLLED BY CORPORATIONS.—WORK OF THE SESSION.

A bill of interest, possibly prophetic of legislation to come in some future Congress, is that of J. F. Shafroth, senator from Colorado, to regulate the quantity of coal lands which may be entered or controlled by associations or corporations. The bill provides that any qualified corporation or association of persons or municipality shall on application to the register of the proper land office have the right to enter by legal subdivisions any quantity of vacant coal lands in the United States, within any state of the Union, not otherwise appropriated or reserved by competent authority, not exceeding 2560 acres, on payment to the receiver of not less than $10 per acre, should the land be situated within 20 miles from any railroad, and not less than $20 per acre if within 15 miles of a railroad. The Secretary of the Interior is to offer such coal lands through advertisement and by competitive bidding, or by such other method as he may by general regulation prescribe, reserving the right to reject any and all bids that he may deem unfair. Improvements or development work to the extent of $10,000 must be made within one year after the award, when patents shall issue therefor. It is further provided that such corporations and associations may not own an area in excess of that prescribed in the act, directly or indirectly, although extra area may be acquired by descent, will, judgment, or decree, but only for two years thereafter and no longer, and in the case of minority or other disability may be held during such time as the court may decree. Violations of the foregoing are punishable by a fine of $10,000 or imprisonment not exceeding 10 years, or both. Furthermore, if such coal lands should come into the control of a trust or other combination illegally operating in restraint of trade, or when excess acreage is acquired contrary to law, the same is to be forfeited to the United States. Half of the money received from the lands entered as described is to go to the state wherein the lands are situated.

Only seven weeks more remain of the short session, and legislation is becoming so clogged, principally on account of the determination of the President to procure the enactment of the shipping bill, that the outlook for the passage of the conservation measures, inclusive of the so-called leasing bill, offers no encourageemnt whatever to those who would like to see the measure passed by the Senate.

Interference with American shipping by England continues to attract considerable attention here. T. J. Walsh, senator from Montana, made a vigorous protest, and said that every detained ship against which a *prima facie* case had not been proved, should be released.

HOUGHTON, MICHIGAN

TONNAGE TAX—COPPER SHIPMENTS—ISLE ROYALE NEW MILL—TAMARACK REGRINDING PLANT—MOHAWK MINE—SILVER FROM CALUMET & HECLA—WOLVERINE OUTPUT.

The ruins of the Isle Royale stamp-mill are being removed rapidly, a large number of men being at work. To the numerous Copper Country people who visited the place shortly after the fire, the clearing away of the large bent girders, twisted pipe, and wrecked tables, jigs, and stamps seemed a hopeless task. As is characteristic of all work in the district, every possible means is being used to clear the site as soon as possible for the erection of the new mill. The Worden-Allen Co., of Milwaukee, which is to build the new three-stamp mill, is facilitating this work by the use of the oxy-acetylene blowpipe. The process of rapidly cutting through huge beams and girders by means of the intense flame generated, is something new, and of great interest to the engineers of Houghton. The Isle Royale is sending 2000 tons of rock per day to the Centennial-Allouez mill at Point Mills. This is a subsidiary property of the Calumet & Hecla.

Employees of the American Bridge Co. who have been constructing the new regrinding mill for the Tamarack Mining Co. at Hubbell have completed their work, and have gone to Hibbing, Minnesota, to construct a 300,000-gal. water tank for the city. When the workmen arrived in Hubbell early in November, it was reported that the construction work on the new plant would be rushed with all possible speed. It is interesting to note that the men spent only six weeks on the contract. The building is 100 ft. wide and 186 ft. long, and 307 tons of steel was used. The building is now ready for the installation of the machinery. The Tamarack regrinding plant is one of the few pieces of construction work which was not delayed by the general curtailment of all operations in the district.

The Mohawk mine is producing the best 'rock' tonnage in its history, and shipments average better than 3600 tons per day. Furthermore, the grade of ore is higher than before, yielding 20 lb. of refined copper per ton.

A shipment of 100,000 oz. silver bullion, valued at nearly $50,000, was made January 8 from the Calumet & Hecla smelting plant at Hubbell. This is the first large shipment from the district. Formerly all the Calumet & Hecla copper was sent to the plant at Buffalo for refining. This eastern plant has been disposed of, and a new electrolytic refinery at Hubbell is now efficiently treating the Calumet & Hecla output, which carries undesirable arsenic and considerable silver.

The Wolverine Mining Co. shows a total of 3935 tons of 'mineral' produced for the last 10 months of 1914. The largest monthly production was 472 tons in June, and the lowest 314 tons in March.

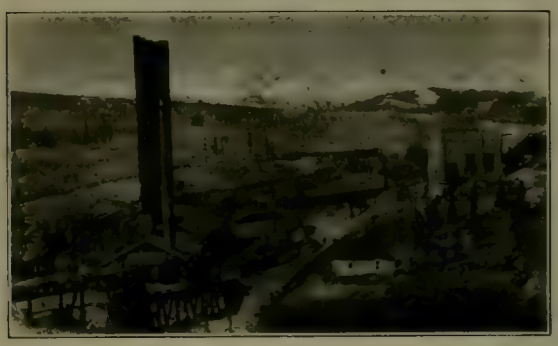
The total shipment of copper by way of the Great Lakes during the past season, from April to the close of navigation, November 18, amounted to 53,933 tons. The copper country ports and the amount shipped from each are as follows: Houghton, 17,514; Hancock, 5329; Dollar Bay, 11,260; and Torch Lake, 19,830 tons. Included in this is one shipment of 101 tons of western electrolytic copper which was sent to Dollar Bay for re-treatment.

There has been a great deal of concern shown recently, both in the iron and copper districts of Michigan, over the proposed state tonnage tax. A large number of upper peninsula delegates met at Marquette early in December to form a permanent organization to oppose the tonnage tax bill. At a recent meeting of the State Grange, however, the advocates and initiators of the bill failed to secure sufficient signatures to force the legislature to consider the proposed law. The defeat of the tonnage tax campaign as far as the present term of the legislature is concerned, is certainly pleasing news to the people of the iron and copper countries.

LEADVILLE, COLORADO

ENCOURAGING RESULTS EXPECTED THIS YEAR FROM THE DOWN-TOWN, PROSPECT MOUNTAIN, TWIN LAKES, AND LACKAWANNA, AND DEEPER SINKING SCHEMES.

The new year begins with four features in mining progress in and around Leadville standing out as the important factors of the future activity of the district. Of these, the one having the most influence upon local conditions is the unwatering of the down-town area, an enterprise that is now in the preliminary stages and rapidly being prepared for operation. At the present time, all of the surface work has been completed, and the plant at the Penrose shaft, through which the water will be pumped, is ready for work. The contractors are timbering the shaft from the surface down to a shallow depth, while the Colorado Power Co. is erecting transmission lines, etc., to get power to the property. The hoist will then be driven by a motor, and the work of timbering down to



YAK MINE, LEADVILLE, COLORADO.

water-level will be started. All of this will be completed early in 1915. The machinery, pumps, motors, and other equipment is expected to be delivered during January, and it is planned to have everything in shape for installing the pumps as soon as they arrive.

The prosperity of the district for the current year and for several years to come is based directly on the success of this scheme. The Company controls a vast area of ground, including such well known producers as the Coronado, Midas, Sixth Street Shaft, Weldon, Bison, Bon Air, P. O. S., and Penrose. The last named, the base of the operations, lies directly on the large vein of zinc carbonate ores that extends from the Maid of Erin southwest through the Bon Air. During the time when this property was last active, many tons of the now valuable zinc was thrown over the dump as waste. It was from this abandoned material that the first shipment of carbonate from the Leadville district was made. It is expected that the ore will be found most extensively in the Penrose and adjoining properties, at the same depth it was found in the Maid, between 700 and 800 ft. The formations in both are about the same, and both are on the ore-shoot, south of the most extensive faulting. Some idea of the extent of this great deposit may be estimated from the developments that have been brought to light by the Western Mining Co., which has been working the northern parts of the vein through the Wolftone shaft on Carbonate hill. This property, which has been the largest producer of zinc carbonate in the world for the past year, has maintained an output of 350 tons for 365 days, a total of 127,750 tons. Mining men who are familiar with the formations in the Penrose and other properties controlled by the Down Town Mining Co., state that the output of the Wolftone will be equalled, if not surpassed, by the production that will be taken from the now drowned area. For these reasons the opening of the Penrose is considered the dominating factor in the future prosperity of Leadville. It will mean an addition of from 600 to 700 men to the present payroll of the district, and an increase of from 500 to 1000 tons of ore produced each month. In addition to the zinc deposits that are to be found in this territory, there are large deposits of silver and iron ores which will prove of great value.

Another large development project is to be launched which will make a great increase in the future possibilities of Leadville. The area lying immediately north of the Big Evans, and the many properties on Fryer, Yankee, and Breece hills known as the Canterbury Hill and Prospect Mountain section, is to be explored by an adit. The territory has been mined slightly near the surface, and some good shipping ore has been produced from the Canterbury and Rosevale properties. No extensive work has ever succeeded, because of the water that has always been tapped at a shallow depth. All of the big ore-shoots that were mined on Fryer hill in the Matchless, Pittsburg, Robert E. Lee, Discovery, and other famous mines of the early eighties, dip to the northeast, directly in a line with the Canterbury ground. The same is true of the veins cut in the properties on Breece hill. This leaves little doubt of their presence under the formations to the north, but they will be found only at considerable depth.

The plan that is now under way to open this large district is to organize a company of local mining and business men, and drive the adit under the territory from the Arkansas valley for a distance of about 5000 ft. This would cut all the veins from Fryer and Breece hills, or make it possible to reach them with a minimum amount of interior shaft work. A depth of from 700 to 2000 ft. will be gained by the bore, and the water question will be easily solved. The proposition is a big one, and one that demands a large amount of capital. However, under the share system, and with men known to be capable and trustworthy for the direction of the work at the head, there is every reason to believe that the undertaking will prove a success. Already a great part of the shares has been spoken for by the active men of the district, and everyone is interested in the enterprise. After the first of the year the work of formally organizing the company will be taken up by the promoters, and it is expected that results will be obtained within the month.

The third feature of the prospective era of prosperity that will dawn in 1915 is the remarkable advance that is being made in the Twin Lakes and Lackawanna districts, in the western range of mountains that have long been overlooked as mining territories. Three large properties are being worked this winter, and all of them are producing some of the best gold-bearing ore that has been found in the vicinity. Along with this the report that there are large deposits of molybdenite ore in the district has recently come in, and no little interest is being taken in this new discovery. During the summer of 1915 good developments are expected from this area, and there is no doubt that a number of mines will be opened and a great deal of milling plant installed.

The last factor of importance that has the appearance of a lasting and beneficial result on the future, is a move on the part of the larger companies in the district to sink their shafts into the lower formations. Four mines are now being put down from 100 to 150 ft. deeper than their present workings. These are the Monarch shaft of the New Monarch Mining Co., the Big Four shaft of the Big Five Operating Co., the Garbutt shaft on Jonny hill, and the President on Breece hill. The fact that good ore has been found deep in the Cripple Creek and other districts of the state gives the impression that the same will be true at Leadville.

Everything points to a banner year for 1915 in the way of opening and developing new ground, which after all is the real test and measure of the life of a mining camp.

PLATTEVILLE, WISCONSIN

Satisfactory Results in the Zinc Districts in December. Course of Prices, Legislation, Ore Production, Buyers, Operators' Views of the Future.

From two points of view especially, December proved the banner month of the year in the zinc mining industry of this field, namely, a much enhanced value received for raw ore, and a decided increase in output regardless of severe winter weather, which hampered deliveries from outlying mines.

The prediction freely made by several of the leading ore buyers of the field that spelter would reach higher prices, possibly 6c. per pound, was nearly verified, the middle of the month witnessing firm quotations at 5.7 to 5.8c. at St. Louis. This condition followed some buying for foreign consumption, and insistent inquiries in the first half of the month, which were lacking toward the close and with which was coupled an almost stagnant demand for metal for home consumption, with the result that prices fell and were well under 5.4c. at the end of the month. With its 'characteristic penchant for pyrotechnical stunts' at unexpected moments, zinc ore reversed itself under declining metal markets, and instead of showing declines, actually made substantial gains, closing out of all proportion to metal quotations, at $48 to $51 per ton for 60% ore, as compared with $36 to $39 per ton at the beginning of the month. A heavy production from the districts of the southern half of the field responded promptly to the improved offerings, although buyers evidently labored under instructions to avoid competition, and deliveries were made through the usual channels of outlet. An increased movement of raw concentrate, the heaviest for any single month of the year, was shown on the weekly car reports published for the field, while a reserve was carried over conservatively estimated at 3000 tons.

Lead ore was in poor demand all the month; pig lead receded from an already weakened position and closed the month on inside business at 3.6c. at St. Louis. Very little ore cleared and production was nominal. About 1000 tons was carried over in anticipation of better markets.

Pyrite was off price, and production and shipments both took a decided drop. The production for the entire year shows a large reduction over the figures published for the output of 1913.

Carbonate of zinc ore producers of the northern districts were given a good market at the beginning of the month, and a fair quantity of ore cleared at excellent prices, the base being $24 per ton for 40% ore, all of which was secured by the New Jersey Zinc Co. The demand was sporadic, and miners were left with an accumulation of several months' active operations. This condition exercised no discouraging influence over those who have placed increased working forces underground for the winter, and a large tonnage of mill feed is piling up. Small operating concerns increased in number and leases were anxiously secured, the incentive being only the hope of a good demand at some future date.

A recent act of the legislature in taxing orebodies has excited a great deal of adverse comment among mining men and capitalists, who might become interested in the field. Many valuable mining properties are now languishing for want of a little financial backing, all because the new law is considered to levy assessments on ore deposits yet undeveloped, and to impose an unfair burden. This has had the direct effect of driving capital out of the field, and operators have been driven to adopt various subterfuges to escape the full effect of this piece of legislation.

The gross production of concentrate for the month aggregated 28,888,782 lb., and net refined ores from separating plants and wet concentrate direct to smelter 16,392,330 lb. The Mineral Point Zinc Works shipped 54 cars of calcined ore to Depue, Illinois, equal to 4,222,500 pounds.

Ore production for the field in December was reported as follows, by districts:

Districts.	Zinc, pounds.	Lead, pounds.	Pyrite, pounds.
Benton	8,006,000	160,000	1,306,700
Galena	6,940,000	61,400	
Cuba	3,826,000		
Hazel Green	3,606,000		
Livingston	3,076,000		
Linden	2,034,000	60,000	
Shullsburg	1,894,000		
Mifflin	1,256,000		
Platteville	1,022,000		
Highland	650,000		
Mineral Point	84,000		
Total	32,364,000	281,400	1,306,700

Sales were distributed among the following buying concerns: Mineral Point Zinc Co., 7763 tons; National Separating Works, Cuba, 2166 tons; Grasselli Chemical Co., 1263 tons; Empire Roasters, 1149 tons; American Metals Co., 865 tons; Illinois Zinc Co., 952 tons; M. & H. Zinc Co., 787 tons; Linden Zinc Co., 446 tons; and Campbell Separating Works, 584 tons.

The northern areas of the field, including the Platteville district, showed up indifferently all through the month, and both output and shipments were unsatisfactory. No prospect, mine development, or construction work was noted here except in the Mifflin district, where two new concentrating plants were started; but even then the production was curtailed, and more than 1000 tons of choice ore was carried over at the end of the month. In marked contrast to all this was noted the activity in the southern half of the field, where new ground was being explored with drills, new mines developed, and new equipments being provided. Operators interviewed at several points in the field appear optimistic as to developments of the future. They expect a higher metal market, and even better prices for ore, within the next 60 days, and apparently this has some backing, as plans are being laid for more elaborate exploration work, mine development, and power and mill construction. The year, despite low prices, has been one of the best experienced by Wisconsin miners, since all operated conservatively, and while profits were small they were carefully husbanded, and left the different concerns in fair condition financially. All look toward a season of prosperity.

CARSON CITY, NEVADA

The report of the state inspector of mines, Edward Ryan, covers the year ended November 30, 1914. It consists of 52 pages, and covers the state generally. There are about 190 mining districts irregularly scattered throughout the state. In the Great Basin, of which Nevada forms the larger part, are a number of north-south ranges of complicated structure, separated by almost an equal number of fertile valleys and some desert. Nearly all of these ranges are mineralized more or less. This makes prospecting attractive. In 1913 there were 786 producers, 82 more than in 1912, yet the value of the total decreased $1,261,022. There was 5,367,211 tons of all ores treated for 570,589 oz. gold, 16,090,083 oz. silver, 90,693,751 lb. copper, 16,344,023 lb. lead, and 14,419,671 lb. zinc, worth a total of $37,097,710. The report deals with mining legislation, mine-rescue and first-aid work, county notes, notices issued to companies to rectify certain necessary points in the mines, details of accidents, and expenditure of the inspector's department, which amounted to $9331. James W. Gaughan is deputy inspector.

There has been some active prospecting and development of quicksilver ores in this state in recent years, and the output increased in 1914, according to the U. S. Geological Survey. The Nevada Cinnabar mine at Ione made a large yield.

THE MINING SUMMARY

The news of the week as told by our special correspondents and reflected by the local press.

ARIZONA

Gila County

Although the Miami Copper Co. has enough money to pay its quarterly dividend, the full amount was not earned during the last quarter, and the directors on January 4 decided not to make any distribution. This is the second dividend to be passed. Operations are still at 50% capacity.

The Old Dominion at Globe produced 1,710,000 lb. of copper in December. The total for 1914 is 30,448,000 lb., against 30,810,000 lb. in 1913.

Mohave County

At 350 ft. in the Gold Ore mine, near Goldroad, a rich streak of ore has been cut, showing plenty of free gold.

Pima County

The Calumet & Arizona company is employing about 400 men on its property at Ajo. It is said that 8 or 10 copper claims of T. Childs have been acquired by the Company for $122,000.——A 4-in. vein of high-grade wolfram ore has been opened by M. G. Levy in the Young American claims in the Ajo district. Some of the ore has been sent to Pittsburgh.

CALIFORNIA

Legislation enabling oil producers to organize and protect the various fields against underground water will be the subject of a meeting called by state mineralogist, F. McN. Hamilton, for January 15, at one o'clock at the State Capitol at Sacramento. There will be representatives from the State Mining Bureau, and a number of prominent oil operators who will aim to present the needs of the oil industry to interested legislators. W. F. Chandler, senator from Fresno, has taken an active interest in the matter. A bill has been drafted by the Mining Bureau, under the supervision of R. P. McLaughlin, who, during the past year directed an investigation of the oil industry.

According to the United States Geological Survey, there were 33 mines and prospects producing quicksilver in the United States in 1914, of which 23 were in California. In 1913 there were 24 producers, of which 18 were in California. The estimated output for California in 1914 was 11,469 flasks, valued at $561,981, against a production of 15,591 flasks, valued at $627,228 in 1913. The output in California in 1914 was the smallest since 1860. The chief producers in 1914 were the New Idria mines of San Benito county, Oceanic of San Luis Obispo county, New Guadalupe and New Almaden of Santa Clara county, St. John of Solano county, and Helen of Lake county. Among smaller producers were the Cloverdale, Little Panoche, Acachuma, Los Prietos, Alpine, Reed, Aetna, Oat Hill, Hernandez, Little Bonanza, Summit, Wall Street, and Knoxville. The output of the famous New Idria, New Guadalupe, and New Almaden mines again showed decreases, but the Oceanic and Helen mines were slightly more productive than in 1913, and the revived Oat Hill and St. John mines, working old material under new managers, made relatively large increases in yield. From present information the production of California will not immediately regain the average output of 21,361 flasks for the period 1902-1913.

Gold output of the state last year was $21,138,500.

Butte County

The Oroville Dredging Co. for the 15 months ended September 30, 1914, shows a profit of $154,000, and $16,000 brought forward from the previous term. Two 12c. dividends absorbed $152,000. Owing to trouble at the Pato property, Colombia, Central America, dividends were suspended for a time, but dredging has been started again. The cost of dredging there is 10.25 to 11.52c. per yard.

Calaveras County

The Oro Water, Light & Power Co. is constructing another dredge on the Mokelumne river, near Camanche, and it will be ready about March 1. The boat, with 6-cu. ft. buckets, was designed by C. G. Leeson, manager of the dredging department of the Company, and a description will be pulblished in the *Press* later on. The 9-ft. boat is averaging 150,000 cu. yd. per month. This was described in this journal of December 13, 1913.

Eldorado County

The old Big Sandy mine at Kelsey has been sampled by A. Crafton, recently in Mexico, and on his report depends whether it will be reopened.——The Rocky Bar gravel claims, on the middle fork of the Cosumnes river in the Mt. Pleasant district, are to be worked on a royalty basis by J. E. White, of Fort Wayne, Indiana, who has a bond from C. E. Wilbur and W. R. Kelly, of San Francisco.

Kern County

According to advice from El Paso, Texas, Phelps, Dodge & Co. has purchased the Pearl and Zenda gold mines in the Amalie district from Joseph Fauset and others of southern California, for between $75,000 and $100,000. A 10-stamp mill and cyanide plant are in working order.

In the news of December 26 it was stated that the Weringer copper mine at Woody had ore reserves amounting to 4000 tons. This really is the quantity on the dump, and sampling underground shows ore worth about $500,000. Cross-cuts from two shafts show wide shoots.

Mariposa County

At the Mountain King mine, in the Merced River cañon, eight miles above Bagby, a new 500-hp. water-power plant is being erected, and the 20-stamp mill is to be replaced by one with 60 head. Improvements will cost about $50,000. Fifty men are employed at the mine, and an equal number on construction. Alexander Hamilton is superintendent and Rudolph W. Van Norden, chief engineer.

Nevada County

From the Jerry Goodwin gravel mine the You Bet company is reported to be extracting rich gravel. There are 16 men employed.——Near Lake City the El Oro Mines Co. is sinking a shaft to open the blue gravel channel at 200 ft. Machinery has been ordered. Fred Phelps is manager.

Shasta County

Assessment work to the value of $4400 has been done on 44 asbestos claims on Mears creek, near Sims.——J. G. Barber, William R. Scott, George Gameble, E. M. Wilkinson, William Holland, E. C. Montgomery, James Bowe, and John Brown, all of San Francisco, have located 1160 acres of placer ground between Gas Point and Igo.——The Shasta Dredging Co. at Horsetown, near the places mentioned, has bonded several farms along Cottonwood creek.

Sierra County

(Special Correspondence.)—The Pacific mine, two miles south of here, has been bonded to the Greenwood Mining & Development Co. of San Francisco. The Pacific and St. Elmo,

the latter mine owned by the Greenwood company, is estimated to contain 2½ miles of lava-capped channel. A double track adit more than 2500 ft. long is to be started in the latter part of May. This adit will eventually reach a length of three miles. Electric locomotives of General Electric Co. make are to be installed after the channel is reached. F. T. Heacock of San Francisco is secretary of the Company, and L. Ferdinand Johnson is consulting engineer.

Table Rock, January 5.

(Special Correspondence.) An examination of the Gray Eagle mine, at Gold Point, was made last week by F. Love and W. H. Hooper of San Francisco, and a large amount of new work has been arranged. A six-foot vein of fair-grade ore was recently cut in a winze, and is being prospected. W. H. Arbuckle is superintendent.——'Pay' gravel has been opened in the Cold Spring mine, near Mount Vernon. The back channel was intersected by a 75-ft. rise from the 350-ft. adit, and considerable gold is present. The gravel is being stored on the dumps until sufficient water can be obtained for washing. ——The shoot of ore recently cut in the Keystone mine, near Sierra City, continues to improve. About two feet of the vein

MAP OF SIERRA COUNTY.

is said to average $10 to $50 per ton.——Work has been resumed at the Gold King mine by C. M. Weldon and associates. The property is in the Alleghany district, and produced rich ore 30 years ago.——The Sixteen-to-One mine is producing good ore, with considerable work progressing in the lower levels. Twenty men are now on the payroll.——An electric power-line is being completed to the Twenty-One mine, and erection of the small mill is making good progress. Crushing will start in the early spring.——The mill at the Kate Hardy mine, in the Forest district, is running steadily on good ore. A. D. Grant is superintendent.——The Brandy City and Neocene companies are operating their hydraulic mines with large crews, and the abundance of snow in the hills favors a long season.

Downieville, January 3.

Siskiyou County

The Gray Eagle mine at Oro Fino has been optioned to Seattle people. The shaft is to be unwatered.——The Oom Paul mill is to start when water is available. A. C. Renfrew is manager.——James Doyle, formerly with the Gladstone and Midas in Shasta county, is examining the McKeen mine near Callahan.——Cold weather has frozen up ditches and flumes in numerous Siskiyou county districts, and many mines are idle because of lack of water.

Tuolumne County

Lee Hamm, working on the Ida Kline claim near Sonora, recently panned $8000 in 10 days from a quartz formation.

COLORADO

Lake County (Leadville)

The mineral production of this district in 1914 is estimated by the *Carbonate Chronicle* as follows:

Ores	Tons
Lead carbonate	181,348
Galena	74,627
Zinc carbonate and sulphide	204,427
Iron	13,415
Silicious	28,800
Total	502,617

Metals:	
Gold, ounces	74,610
Silver, ounces	3,851,695
Lead, pounds	25,043,570
Copper, pounds	2,523,763
Spelter, pounds	79,398,172
Total value (9,040,359 in 1913)	$9,087,628

The output to date is valued at $415,538,688.

A vein of molybdenite is reported to have been cut in the Twin Lakes district.——The Western Mining Co., through its manager, S. D. Nicholson, gave each of the 250 employees a turkey for Christmas. A bill in equity has been filed against this Company and others for $6,252,000 damages, by R. E. Elder and F. E. Mann, executors of the will of G. W. Elder. The damages are for minerals and ore claimed to have been taken from the mines by the respondents during a period of years from 1899 to December 3, 1914, during which, it is charged, the lease was void.——The Yak Mining Co., at Christmas, presented each of over 125 employees with a postal savings bank book crediting his deposit with a sum of equal to 2% of his annual wages.

San Miguel County

It is reported that the Tomboy company has purchased the Revenue claims near Telluride.

Summit County

This county's branch of the Colorado Metal Mining Association has elected R. M. Henderson, W. H. Green, E. C. Sutton, G. H. Gibson, and O. K. Gayman to represent the county at the state convention held at Denver on January 11. Mine legislation and taxation, bureau of mines, school of mines, and state geologist were subjects to be discussed.

All dredges at Breckenridge save one, *Tonopah No. 3*, are stopped on account of the cold weather.

Teller County

The Portland company will pay 2c. per share on January 20, amounting to $60,000. The annual meeting will be held at Cheyenne on February 15.——Lessees at the Abe Lincoln mine are extracting a good tonnage of ore.——Allen L. Burris, president of the El Paso Consolidated company, has resigned. He has issued a report on the Company's condition and cause of his retirement, the latter being a question of policy. The equipment to replace that destroyed by fire should be ready for work on February 1.

IDAHO

Shoshone County (Coeur d'Alene)

The suit of Jonathan Bourne, Jr., and the Ontario Mining Co. *v.* the Stewart Mining Co., started before Judge John M. Flynn at Wallace on January 4. Extralateral rights are the issue, and a great array of legal talent and mining engineers are in attendance. The Stewart has admitted a trespass of 3353 sq. ft., leaving 3560 sq. ft. to be settled.——The Interstate-Callahan company is looking for a suitable site for the mill contemplated.

MISSOURI

Jasper County

A 350-ton mill is being erected for the Dog Mining Co. on the Sucker Flat area. The shaft is 152 ft. deep, and the 25% ore is opened by five drifts.

MONTANA

Fergus County

The Barnes-King company's December output was 5500 tons for $40,000.

Jefferson County

The Elkhorn adit of the Boston & Montana Development Co. is in about 1200 ft., and at 1170 ft., 15 to 18 in. of ore containing molybdenite is being opened. Other veins in the mine carry this mineral.

Silverbow County

The Great Falls refinery is operating again, producing copper on order for the Chicago, Milwaukee & St. Paul railroad for the electrification of its line. On account of an accident at the Leonard mine of the Anaconda, the Original will continue until the trouble is overcome, in about two weeks. Two diamond-drills of the Anaconda are boring to 200 ft. in the Butte-Duluth, the latter being under option to the former. Soft ground is hindering drilling.——At 2400 ft. in the Pilot-Butte 12 in. of 6% copper ore has been cut near the shaft.

NEVADA

Esmeralda County

The estimated production of the Goldfield Consolidated Mines in December is as follows: ore treated, 29,050 tons; gold yield, $359,239; operating expense, $186,000; net realization, $173,239. The output for the year was approximately 337,391 tons worth $2,093,820, with a profit of $1,829,159. The yield to date is 2,115,695 tons for ore valued at $63,773,003, and dividends $27,932,087.——On March 1 the Jumbo Extension company will distribute 5c. per share. The estimated yield in December was $125,000, leaving a profit of $100,000. Cash and ore in transit on January 1 was worth $220,000.

Humboldt County

Some specimen ore is being extracted from the National mine at National.——Gross receipts from the Seven Troughs Coalition mine in December were $55,000. Cash on hand amounts to $100,000, and a dividend, probably 5c. per share, or $70,000, will be paid on March 1.

Lincoln County

The total output of the Pioche district in 1914 was about 2200 cars of ore. The current year's production is expected to be much greater. Two new mills are proposed, one for the Amalgamated Pioche Mines & Smelting Co., and the other for the Yuba Leasing & Development Company.

Nye County

Five mines at Tonopah produced 10,282 tons of ore valued at $211,036 last week.——The Tonopah Mining Co. is to acquire the White Caps mine at Manhattan if it proves of sufficient value on examination.——As most of the miners at Tonogold have not enough capital to install hoists for deeper work, prospecting has been almost suspended for some time. The Arizona Leasing Co., W. J. Bathurst in charge, has cut 6 ft. of ore at 80 ft. Two inches of this assays $49.70 per ton.

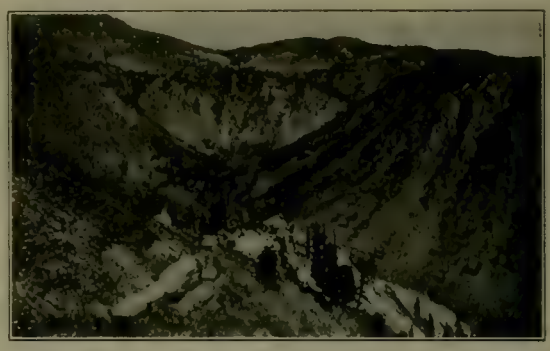
White Pine County

The Ely district is quiet, the Nevada Consolidated continuing on a 50% basis, and only a few lessees working, probably more than in the past. The Hayes claim, near Star Pointer, shipped a car of $40 gold-silver ore recently. Guy Gallagher sent out a car of $67 gold ore from Camp's claim in Heath cañon, Railroad valley, Nye county, and Peddler Bros. are extracting zinc ore, averaging 35% metal, from just above Lane City, near the Consolidated Coppermines property.

OREGON

Baker County

The Baker Mines Co.'s mine and mill, 18 miles west of Copperfield, on the Snake river, are described by Will C. Higgins in the December 30 issue of *The Salt Lake Mining Review*. The property is in precipitous and picturesque country. The Last Chance is the principal mine worked. It is one mile from, and 1700 ft. above the mill. The main adit is in to a vertical depth of 700 ft. A Bleichert aerial tramway, 5500 ft. long, carries ore from the portal to the mill. The prevailing rock is greenstone, and the two veins of oxide ore are four feet wide.



LAST CHANCE MINE OF THE BAKER MINING CO., AT CORNUCOPIA.

The 20-stamp mill contains also amalgamating plates, Dorr classifier, 30-ft. sand leaching vats, 30-ft. Dorr thickener, two 16 by 20-ft. Dorr agitators, two Moore thickeners, 20 and 30 ft. diameter, a Portland filter, and Merrill precipitation plant. John M. Baker is general manager.

Josephine County

According to G. T. Thrasher, of Phoenix, Jackson county, the placer districts of southern Oregon show increased activity, especially in the northern part of Josephine county. Gravel bars of many creeks are being sluiced.

SOUTH DAKOTA

Lawrence County

Shaft sinking has been started at the Echo mine at Maitland, A. J. Simmons being in charge. Men are employed erecting buildings, and the machinery to be installed includes a motor-driven hoist and air-compressor. New Hampshire people are interested in the Company.——At the Heidelberg, in Two Bit gulch, east of Deadwood, according to the manager, A. T. Ross, $12 ore has been opened 500 ft. across the gulch from the workings which have produced good ore.——Good progress is being made with construction of the Rattlesnake-Jack mill near Galena. C. S. Ruth is in charge.——Water has been drained from the Hidden Treasure shaft and cross-cutting is under way at 200 ft. Stewart Thompson is manager.

UTAH

In its issue of January 3, *The Salt Lake Tribune* devotes several pages to a detailed review of mining in the state in 1914. Including $6,962,003 paid in dividends last year, the total of all mines to date is $110,716,321. The Bingham district produced 8,077,856 tons of ore, against 9,190,374 tons in 1913. Judging by the growing inquiry regarding several districts, a revival of the mining industry is predicted.

Juab County

The Eagle & Blue Bell mine is producing about 2000 tons of ore per month. At 275 ft. from the shaft, at 1700 ft. depth, the shoot being mined at 1550 ft. has been cut.

PIUTE COUNTY

The potash and alunite deposits near Marysville are to be the scene of greater development this year. The Florence Mining Co., of Philadelphia, has let a contract for the extraction and haulage of 350 tons of alunite from its property to the D. & R. G. station at Marysville. The ore will be sent to Cincinnati, Ohio, for testing purposes.

SUMMIT COUNTY

The Snake Creek tunnel is in about 10,500 ft. The progress in December was only 296 ft., due to holidays and installing a new compressor. During 1914 the advance was 3751 ft. The face is now in diorite dipping south, with a course-grained calcite hanging wall.

WASHINGTON

Within a radius of 150 miles north and east of Spokane nearly $35,000,000 of metals was produced in 1914. The figures are as follows:

Coeur d'Alene (Idaho) mines	$24,130,900
Trail (B. C.) smelter	5,848,478
Grand Forks (B. C.) smelter	2,389,620
Greenwood (B. C.) smelter	910,895
Sundry mines of Washington, northern Idaho, and British Columbia (estimated)	1,250,000
	$34,529,893

Smelter productions are official from the managements of the three companies. The Coeur d'Alene output is based on figures by Stanly A. Easton, manager of the Bunker Hill & Sullivan company, and by Frederick Burbidge.

CANADA

BRITISH COLUMBIA

Rossland mines in December shipped 27,012 tons to the smelters, an increase of 2527 tons over November.

At 900 ft. below the surface, and 1200 ft. from the portal of the adit, over 10 ft. of ore assaying $39 per ton gold and 75c silver has been cut in the Argo mine. This property is in Greenwood and near the British Columbia Copper smelter.

At Surf Inlet, the Tonopah Belmont company, with F. W. Holler in charge, continues considerable development. This will cost $150,000 up to July of this year, when the option expires. About 50 men are employed. Adits have proved over 200,000 tons of $8 ore. If the mine is bought, the Company will erect a hydro-electric plant and a 500-ton mill.

ONTARIO

At Porcupine the Hollinger produced 18,645 tons of $13.22 ore during the period ended December 2, with a profit of $152,664. Costs were $3.40 per ton. Bonuses paid to employees during 1914 amounted to nearly $12,000.——Plans are being prepared by J. Houston, manager of the Schumacher, for a 50-ton mill to be constructed in the spring.——Faulting displaced the Porcupine Crown vein 50 ft. at the 500-ft. level, but driving has opened ore equal to that in the upper levels. Work for the current year includes shaft-sinking to 800 ft. and a winze on the vein below 500 ft. Broken ore at 200 and 300 ft. amounts to about 25,000 tons. The mill treated 125 tons per day in December. The average monthly output last year was $50,000.

At Cobalt the Nipissing high and low-grade mills treated 175 and 6919 tons of ore, respectively, in December, yielding silver worth $204,034. Bullion shipped was worth $535,864. Mine development was satisfactory.

COLOMBIA

The Pato dredge recovered $62,500 from 60,500 cu. yd. during the two weeks ended December 8.

A cablegram from the American consulate at Barranquilla states that the commercial situation is slightly better, financial situation unchanged, exports normal, and many unemployed.

KOREA

The Oriental Consolidated company's output in October was $110,450, from 21,505 tons of ore. The net profit above operating, development, and improvements was $56,871. The Tabowie 80-stamp mill was hung up 10 days on account of general repairs, the Kuk San Dong 40-stamp mill was closed for the full month through a shortage of ore, and the East Candlestick 10-stamp mill was down 13 days for the same reason. The output in November was $151,425 from 28,056 tons, and in December $148,216.

The Seoul Mining Co., operating the Suan concession in Whang Hai province, reports the following results for December 1914:

Stamps working	40
Time, days	28
Ore crushed, tons	6,320
Total recovery	$82,400
Operating expenses	26,000
Net earnings	56,400

The 2000-kw. steam-turbine electric generating plant, erected by the Company at tidewater, 52 miles from the mine, has been completed, and commencing with January 7 the mill and mine plant will be operated by electricity instead of by steam as heretofore. A reduction in operating costs is anticipated.

JAPAN

(Special Correspondence.)—The most disastrous coal mine explosion in the history of Japanese mining occurred at the Shin-Yubari mine, Hokkaido, November 28. The total number killed was 422, including a number of engineers, assistant engineers, and foremen. The colliery includes two mines, the explosion being in the Wakanabe, which is in a Tertiary coal and is opened by an adit 6000 ft. long, and a slope 2000 ft. long at 10° dip. The explosion occurred in an entry off this slope and wrecked the workings throughout. The compressor house at the entrance to the slope was burned, and men repairing brickwork in the incline were blown to the surface and into unrecognizable fragments. Of the dead, 166 bodies were recovered before December 3, when all entrances to the mine were closed and water from the river turned into the lower workings to drown the fire which followed the explosion. The latter is believed to have been caused by fire damp.

Tokyo, December 15.

MEXICO

SONORA

Six inches of rain fell at Nacozari during the third week in December, this being about equal to the annual precipitation in that district. Considerable damage was done to the railway and property of the Moctezuma Copper Company.

NACOZARI AS SEEN FROM MOCTEZUMA MILL, SHOWING TIMBER YARD OF THE COMPANY, ROUNDHOUSE OF THE NACOZARI RAILROAD, AND THE POWER HOUSE.

PERSONAL

J. D. Irving is at Butte, Montana.

J. W. Neill was in San Francisco this week.

Robert Nye was in San Francisco this week.

M. K. Rodgers was in San Francisco Wednesday.

C. M. Eye has been down to Manila from Benguet.

Robert Stichr has been at Long Beach, California.

Arthur Gibson has returned from Sonora, California.

W. E. Saunders passed through San Francisco this week.

C. W. Purington was in New York last week and has gone to Boston.

Ernest Levy, general manager of the Le Roi No. 2, British Columbia, left for England on January 9.

W. W. Johnson, of the Union Construction Co., was in New York last week and has returned to San Francisco.

J. C. Pickering, formerly of the Ernestine Mining Co., at Mogollon, New Mexico, is now at San Remo hotel, New York.

E. Gybbon Spilsbury has returned to New York from Arizona, his plans for work having been interfered with by floods in the desert.

Wakamatsu Yokoyama passed through San Francisco, on his way to Boston, where he will take up special studies at the Massachusetts Institute of Technology.

C. G. Leeson, formerly manager of the dredging department of the Oro Water, Light & Power Co. has been made manager of both the Oroville and Mokelumne divisions and the New York machine shop.

A complimentary dinner was given to F. G. Cottrell at Hotel Plaza, New York, on January 15, by the American Institute of Mining Engineers, American Electro-Chemical Society, and Mining and Metallurgical Society of America.

Officers for 1915 for the San Francisco section of the A. I. M. E. elected last Monday evening were as follows: chairman, G. H. Clevenger; vice chairman, C. W. Merrill; secretary-treasurer, J. C. Ray; additional members of the executive committee, F. W. Bradley, A. C. Lawson.

A. E. Drucker has gone to Colombia to superintend construction and starting of a 30-stamp mill for the Frontino & Bolivia G. M. Co., Ltd. The stamps will be followed by leaching and a counter-current decantation slime-plant on the Dorr system. It is expected that the work will occupy nine months.

Frederick Laist has been made metallurgical manager for the A. C. M. Co. at Great Falls and Anaconda. He will have general supervision of construction and technical affairs. The local operations and business at the plants will be in charge of C. W. Goodale and E. P. Mathewson as heretofore. L. V. Bender becomes general superintendent at the Washoe plant, with Harry S. Ware as assistant.

Schools and Societies

The Institution of Mining and Metallurgy held the first general meeting of the 24th session in London on November 19. The paper, 'Persistence of Ore in Depth,' by T. A. Rickard, was discussed.

The University of California announces a series of lectures on mining and ore treatment in lieu of the course, Mining 102. The following will be the lecturers: H. Foster Bain, J. A. Burgess, F. G. Cottrell, Lindsay Duncan, William Durbrow, James M. Hyde, R. A. Kinzie, F. C. Lincoln, C. W. Merrill, Fred Searls, Jr., Whitman Symmes, C. E. van Barneveld, and George J. Young.

MINERAL STATISTICS

GOLD AND SILVER

Preliminary estimates by the Mint and U. S. Geological Survey as to the production of gold and silver in the United States during 1914 are as follows:

State or territory.	Gold, fine oz.	Value.	Silver, fine oz.
Alabama	590	$ 12,200	100
Alaska	766,744	15,850,000	398,500
Arizona	218,113	4,508,800	4,306,600
California	1,037,537	21,447,800	1,744,500
Colorado	961,748	19,881,100	8,612,900
Georgia	552	11,400	100
Idaho	51,568	1,066,000	12,689,500
Illinois	.....	.....	1,800
Michigan	.....	.....	404,500
Missouri	.....	.....	60,000
Montana	190,361	3,935,100	10,746,000
Nevada	532,309	11,003,800	14,814,200
New Mexico	58,418	1,207,600	1,682,100
North Carolina	5,752	118,900	1,300
Oregon	77,134	1,594,500	126,700
South Carolina	295	6,100	100
South Dakota	353,621	7,310,000	180,500
Tennessee	285	5,900	95,400
Texas	498	10,300	601,000
Utah	153,842	3,180,200	11,397,500
Virginia	48	1,000	1,000
Washington	29,383	607,400	54,100
Wyoming	106	2,200	100
Philippine Islands	51,282	1,060,100	9,700
Porto Rico	150	3,100	1,500
Total	4,490,336	$92,823,500	67,929,700

In 1913 the gold output was valued at $88,884,400, and silver 68,801,500 ounces.

IRON ORE

The quantity of iron ore mined in the United States in 1914 is estimated to have been between 41,000,000 and 42,500,000 long tons, and the quantity shipped from the mines to receiving ports and iron manufacturing centres between 39,500,000 and 41,000,000 tons, according to E. F. Burchard, of the Survey. These estimates are based on reports from 52 of the important iron mining companies which represent the principal iron producing districts, and whose combined output in 1913 was more than 90% of the total tonnage of iron ore mined in that year.

In the Lake Superior district, where about 85% of the domestic iron ore is mined, the average decrease in production was about 37%, thus indicating a total production for that district of about 32,915,000 tons in 1914, compared with 52,518,158 tons mined in 1913. The shipments of ore from this district apparently decreased about 34%, and accordingly the shipments should approximate 32,790,000 tons in 1914, compared with 50,168,134 tons in 1913.

According to the preliminary reports, stocks of iron ore at the mines apparently increased more than 500,000 tons during 1914, so that the total stocks at the close of 1914 should range between 13,400,000 and 13,500,000 tons, compared with 12,918,633 tons on hand at the close of 1913.

Officials of the iron mining companies are almost unanimous in reporting great depression of trade during 1914. Prices generally were 50 to 75c. per ton lower than in 1913, as low as or lower than those of 1912 and 1905.

THE MARKET PLACE

Weekly Summary of Prices of Shares and Metals

Metal Prices

San Francisco, January 14

Antimony	15 — 15¾
Electrolytic copper	13½ — 13¾
Pig lead	3.95 — 4.00
Quicksilver (flask)	$50.00
Spelter	7 — 7¼
Tin	34½ — 36
Zinc dust, 100-kg. zinc-lined cases	9

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, January 14.—Copper is firm, lead quiet, and spelter strong.

COPPER

Prices of electrolytic in New York, in cents per pound.

Apr.	15.22	14.19	Oct.	16.31	11.10
May	15.42	13.97	Nov.	15.08	11.75
June	14.71	13.60	Dec.	14.25	12.75

The copper market was weak, but a large amount of business resulted in a slight advance. Exports during the week ended January 2 were 12,051,892 lb. The Anaconda company's yield in 1914 was 225,645,000 lb., and Calumet & Arizona, 52,770,000 pounds.

It has been computed that only nine of the principal American copper companies are paying dividends under present conditions. These are Anaconda, Calumet & Arizona, Chino, Old Dominion, Phelps, Dodge & Co., Quincy, Tennessee, Utah Copper, and Wolverine.

According to a 'Daily Consular Report' from Yokohama, Japan, dated November 3, the condition of the copper market is worse than ever, with no prospect of relief. Latest press quotations for electrolytic copper are 29 50 yen per picul (11c. per lb.), and 98% quality at about 28 yen (10.46c. per lb.), but these quotations are nominal, as there are no buyers. The leading mine owners have hitherto exported their output, the home market being supplied by the smaller mines. The suspension of exports, however, has confined the large operators to the home market, which they have congested with enormous stocks. In the consequent slump the price has fallen so low that it does not cover cost of production. A proposal is therefore afoot among mine owners to cease smelting until the congestion is relieved.

COPPER PRODUCERS' ASSOCIATION

This Association, which, up to the commencement of the war, collected and published monthly statistics on the copper situation, voted to go out of existence on January 13.

LEAD

Lead is quoted in cents per pound or dollars per hundred pounds, New York delivery.

Date.		Average week ending

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below.

Week ending			
Dec.	17	Dec. 31	52.50

	1913	1914.		1913.	1914
Jan.	63.01	57.58	July	58.70	54.90
Feb.	61.25	57.53	Aug.	59 32	54.35
Mch.	57.87	58.01	Sept.	60.53	53.75
Apr.	59.26	58 52	Oct.	60.88	51.12
May	60.21	58.21	Nov.	58.76	49.12
June	59.03	56.43	Dec.	57.73	49.27

Silver production of the United States in 1914 is estimated at 67,929,700 oz. The steamer 'Mongolia' took silver worth $158,142 (320,000 oz.) to China on January 9. In December the Nipissing company of Cobalt exported 1,093,510 oz. to England, this being mine and custom ore products stored. While somewhat sensitive, the market is fairly steady.

TIN

Prices in New York, in cents per pound.

Monthly averages.

	1913.	1914.		1913.	1914.
Jan.	50.45	37.85	July	40.70	31.60
Feb.	49.07	39.76	Aug.	41.75	50.20
Mch.	46.95	38.10	Sept.	42.45	33 10
Apr.	49.00	36.10	Oct.	40.61	30.40
May	49 10	33.29	Nov.	39.77	33.51
June	45.10	30.72	Dec.	37.57	33.60

There is little of importance to note with regard to this metal, prices being steady at about 33.50 cents.

METAL PRICES IN GERMANY

The following prices were fixed by the German government on December 14: best quality copper, 21.45c.; aluminum, 34.93c.; antimony, 16.11c.; tin, 51c.; and nickel, 49c. per pound.

Platinum in England is £9 5s., or $44.40 per ounce., and bismuth, 10s., or $2.40 per pound.

COMPANY REPORTS

MT. ELLIOTT COPPER COMPANY, LTD.

This Company operates in Queensland, Australia, and the report covers the year ended June 30, 1914. Smelter returns were as follows:

Details of operation.	1914.	1913.
Ore treated, tons	37,875	41,633
Copper produced, pounds	8,762,880	10,373,440
Gold, ounces	6,266	8,757
Silver, ounces	8,251	7,285
Net profit	$259,000	$682,000

A dividend of $1.20 per share absorbed $178,000. The surplus was $1,052,000. Ore reserves are estimated at 33,750 tons of 11%, and 500,000 tons of 3% ore. A concentrating plant is needed for the latter grade. A consolidation of certain properties in the district has been accomplished, and a central smelter is proposed.

ST. JOHN DEL REY MINING COMPANY, LTD.

The report of this Brazilian company is for the half-year ended August 31, 1914. The mill treated 95,000 tons of ore yielding gold and silver worth £225,514 in London. All charges totaled £154,064, or $8.44 per ton, leaving £60,074. Dividends amounted to £25,900. Investments of the Company in English and Argentine railways are valued at £96,472.

The superintendent, G. Chalmers, stated that all mine entries and machinery were in good condition. The Sirocco fan gave more air as the result of increased speed and removal of obstructions in the air-ways. There were 180 accidents, four of which were fatal. There were 36 accidents among these due to blistering rock, two being fatal. On horizon 18 the lode has been opened a total of 1150 ft. Horizons 13 to 18 produced 97.34% of the ore. Filling put into the mine totaled 68,622 tons. Sorting rejected 1.75%. Labor is abundant owing to the Brazilian government failing to raise a loan, and also the European war. The Chalmers & Williams tube-mills did well, but the shallow fluted liners in one mill are not as efficient as the Morro Velho design in the other mill. Hadfield steel is the most durable yet tried. The Burt filter is receiving a thorough test. The tramway, electric power plants, transport department, hotel, and medical department all gave satisfactory results. Stores on hand are worth £90,000.

CHAMPION REEF GOLD MINING CO. OF INDIA, LTD.

'Persistence of Ore at Kolar,' India, was the title of an article in the *Press* of December 19, by T. A. Rickard. From the longitudinal section of the mines there, the underground work of the Champion Reef will be understood better. Since 1892 this great property has produced 3,396,119 tons, yielding £11,147,537, and £4,157,633 in dividends. During the year ended September 30 1914, the period covered by his report, the output was 216,934 tons for £527,590, of which £138,667 was paid in dividends, or 53⅓ per cent.

The superintendent, Henry J. Gifford, reported as follows: There were 142 Europeans, 103 Eurasians, and 6384 natives employed. Development totaled 17,334 ft. Garland's shaft was sunk to 4461 ft. On No. 45 level of Glen shaft, the drift opened 2 ft. of $45 ore for 207 ft. The circular shaft should be completed early in 1915. Shaft repair has been generally heavy as usual. Pumping was not so heavy on account of only 21.94 in. of rain, 13.85 in. less than in 1912-13. Mine ventilation was improved. Ore reserves are estimated as 477,384 tons, an increase of 73,259 tons.

Out of 255,943 tons mined, 39,009 tons was sorted as waste, leaving 216,934 tons for the stamp-mill, an average of 141.6 stamps working. Amalgamation recovered 97,989 oz. fine gold. The extraction was 77.22%. The tube-mill plant has started work. The sand and slime plants treated 181,063 and 51,872 tons of new and old material, assaying $2.76 and $1.76 per ton, with 62.6 and 88.3% recovery, respectively. No. 2 cyanide plant treated 101,559 tons of old sand and slime, averaging $2.72 per ton, with 47.9% recovery. The total gold saved in all plants was 124,497 oz., or $11.45 per ton of ore milled.

The report also contains a great deal of information on the mine, mills, and equipment. It may be mentioned that air-blasts were less frequent than formerly.

THE CONSOLIDATED MINING & SMELTING COMPANY OF CANADA, LTD.

This British Columbia company is one of the most important in Canada, and the report covers the year ended September 30, 1914. The general manager, R. H. Stewart, reported as follows:

Conditions at the 12 mines operated, generally speaking, have been satisfactory, with a prospect for increased tonnage had it not been for the closing of a number of properties owing to the unsettled state of metal markets. Heavy accumulations of refined metals have been made, which may have to be held for a time, or until the markets resume more

ELECTROLYTIC LEAD REFINERY, TRAIL SMELTER, B. C.

normal conditions. The net profit for the year was $474,012, after writing off $193,150 for depreciation and charging to profit and loss $492,466 spent during the period in mine development. Four dividends, totaling $464,376, or 8% on the capital, were paid, leaving $9636 for the current year.

Development amounted to 33,146 ft. of general work, and 28,897 ft. of diamond-drilling. The mines at Rossland continue to show an increase in the amount of ore available, the greater part being due to ore developed in the Le Roi. The Sullivan claims at Kimberley show a large quantity of complex zinc-lead ore, some of which can be shipped and smelted for lead, while the zinc portion, worth $20 per ton, is not available. Several new properties were purchased.

The smelter at Trail treated 374,771 tons of mixed ores, yielding 129,083 oz. gold, 2,568,301 oz. silver, 34,617,318 lb. lead, and 3,645,997 lb. copper, worth $6,000,662. Contributing mines were as follows: Copper-gold-silver ore: Centre Star, 172,379; Silver King, 16,031; and Le Roi, 80,499 tons. Lead-silver ore: Sullivan, 30,919; St. Eugene, 1217; Molly Gibson, 7; No. 1, 5790; Highland, 1346; Maestro, 262; Richmond-Eureka, 541; Lucky Thought, 36; and Ottawa, 342 tons. The tonnage smelted showed an increase in the average per month over the last financial year of about 4090 tons. Improvements to the plant were published in this journal of January 9. Like the Granby Consolidated and British Columbia Copper companies, this Company's work is of great importance.

New Machines and Devices

An Automatic Aerial Tramway for Carrying Ore

In the state of Durango, a short distance to the west of the city of Durango, there is a large mining district, which is separated from the city of Durango, and consequently from the railroad, by the high range of the Sierra Madre mountains. It is, therefore, almost impossible to get heavy machinery into this district from this side. To the west the country is also mountainous, but not so difficult of passage. Consequently, most of the heavy freight for this district is taken overland about a hundred miles from Mazatlan, which is a port of call for most of the Pacific coast steamers, as well as a station on the extension of the Southern Pacific railway. Even over this route all machinery must be sectionalized so that it may be handled easily by means of pack-mules.

TRANSPORTING A TRAMWAY THROUGH MOUNTAINS OF DURANGO.

The San Luis Mining Co., operating mines near San Dimas, has installed an aerial tramway to transport ore from the mine to the mill. This tramway was furnished by the A. Leschen & Sons Rope Co. of St. Louis, Missouri. The distance between the tunnel mouth and the mill is 2800 metres, and the fall in this distance 526 metres. The capacity required was 10 tons per hour, and this was secured by using 36 carriers, each having a capacity of 6 cu. ft. of material. A 25-mm. diameter patent flattened strand steel rope is used for the loaded carriers to travel over, and a 22-mm. diameter rope of the same type for the returning empty carriers. A 16-mm. rope of the same construction is used as the traveling rope to which the carriers are attached and which runs at a speed of 91 metres per minute. The tramway operates by gravity and is controlled by means of band brakes. The ore being carried down serves as the lifting force for the return of freight. The country over which the tramway is built is exceedingly rough, there being many sharp pinnacles and deep gulches with steep slopes.

The rope and machinery for this tramway was shipped by water to Mazatlan and from there carried overland to the mine. The machinery was all sectionalized so that no piece weighed over 135 kg., and very few pieces over 70 kg. The rope was shipped in single lengths between the tension points. In this case it was necessary to erect but one intermediate tension station, and the 25-mm. and the 22-mm. rope were each shipped in two lengths about 1200 and 1500 metres in length. These ropes were coiled in such a manner that one mule would carry two coils, there being then a length of about 5 metres to the next mule, and then again two coils, and so on. This method of transporting the rope is clearly shown in the illustration. Since timber is very expensive in this region a large part of the construction work consists of masonry. This includes not only the bins and terminal structures; even some of the towers were built of masonry. Notwithstanding the extremely rough nature of the country over which the tramway was built, construction work went forward with great rapidity, and the tramway was soon in operation. A distinguishing feature of this style of tramway is that but one man is required for operation, he being stationed at the upper or loading terminal. At the discharge end the operation is entirely automatic.

Commercial Paragraphs

THE AIR MOISTENER CO., Chicago, Ill., is distributing a small pamphlet entitled 'The Steamo Air Moistener.' The device is automatic, noiseless, and is claimed to bring about a reduction in the amount of fuel used.

THE BUED HIGH COMPRESSION RING CO., Rockford, Ill., has published a directory of piston ring sizes. The rings are made of a special mixture of the best gray iron, are elastic, will withstand heat, and will glaze to a glass-like smoothness.

CHICAGO PNEUMATIC TOOL CO., Chicago, Ill., in a recent publication, Bulletin No. 24-K, describes the 'Chicago Pneumatic' fuel oil engine driven compressor class N-SO. This machine has many new features and is made in both stationary and portable types.

MESTA MACHINE CO., Pittsburgh, Pa., has distributed a bulletin devoted to the Mesta automatic plate valves. The valves are especially designed to meet the requirements of blowing engines and compressors, and are equally well adapted to the requirements of high and low speed engines.

THE MERRILL METALLURGICAL CO., San Francisco, has recently secured a large contract for Merrill automatic sluicing slime filters from the Aurora Consolidated Mines Co., of Aurora, Nevada. The equipment will include three 124-frame 3 by 4 by 2½-in. filters of the most improved design, and will have a minimum capacity of 500 tons of slime per day.

The Copper Producers' Association 131

ARTICLES

CALIFORNIA PETROLEUM IN 1914.
By R. P. McLaughlin 132
The California production in 1914 was greater than that of any previous year, and represented about 40% of the total output of the United States. Mr. McLaughlin analyzes the California production in this article and shows many details regarding the status of the industry in the different oilfields of the state.

ELECTRIC MINE LOCOMOTIVES.
By E. B. Wagner 134
The electric mine locomotive has found a wide application in the field of mining and the allied industries, and details of its construction and operation are presented.

ORE TREATMENT AT CRIPPLE CREEK: A REVIEW.
By P. Henry Argall 135
A review of the metallurgical conditions existing in Cripple Creek district at the close of the past year prove that the metallurgical problems which have been presented by the sulpho-telluride ores have been successfully solved. Ores assaying from $2.50 to $4 are now being profitably treated. The history of the progress which has been made presents many interesting and amusing features as outlined by Mr. Argall.

DANISH TUBE-MILL PEBBLES AND SUBSTITUTES.
By Jay A. Carpenter 139
The subject of the Danish pebble and its substitute is an interesting one to the mill operator; and in the present article the results of a thorough investigation of this subject are presented. It is curious to note that while French pebble, ore, steel balls, artificially rounded flints, and the like have been tried in various parts of the world, the Danish pebble, although an expensive item in many districts, continues to be used largely in tube-milling operations.

MINING IN THE BELGIAN CONGO 142
An abstract from the recent circular issued by the Union Minière, a subsidiary of the Tanganyika Concessions Ltd., showing the operations of the Company during the past year.

MINING IN NEWFOUNDLAND.
By An Occasional Correspondent 143
While the iron ore deposits of Newfoundland have been well known in many markets, but little publicity has been given the work which is being conducted in this, England's oldest colony. The iron and copper deposits have proved to be of considerable importance, and a summary of the work which is being done, is presented.

THE COPPER BEDS OF THE COEUR D'ALENE.
By George Huston 145
The so-called copper beds of the Coeur d'Alene have been the object of study by the author for over a period of seven years. His observations have been made in the most thorough manner, and the commercially mineralized beds, consisting of highly silicious quartzites, have been the subject of particular investigation.

PHILIPPINE DREDGES. Page.
By Frank B. Ingersoll 148
Gold dredging industry in the Philippines has grown in the past six years from nothing to about three-quarters of a million dollars in 1913. At the present time some of the largest operators in the world are invading this field, and the future of the industry is most promising.

ORIGIN OF THE IRON ORES AT KIRUNA, SWEDEN.
By Reginald A. Daly 148
A summary of the field data recently collected regarding the origin of the iron ores at Kiruna.

PERMANENT SURVEY STATIONS.
By John H. Eggers 149
Where survey stations are repeatedly referred to, it is well worth while to establish permanent survey points, some helpful suggestions regarding the construction of such points, together with a convenient card system, are presented in this article.

NEW CORNELIA TONNAGE 150
An estimate of the tonnage available for steam-shovel mining.

SELF-DUMPING BUCKET 151
A useful device whereby economies may be effected by use of an overhead wire rope arranged for hoisting, transporting, and dumping material.

MOISTURE IN BLASTING POWDER 151

THE REGIONAL ALTERATION OF OIL SHALES.
By David White 151
A study of the distribution of petroleums and their salient features.

ATTEMPTS to close the smelter at Thompson, Nevada, because of alleged damage due to smelter fume trouble have been defeated for the present by decision by the court that a preliminary injunction cannot be granted in such cases upon general allegations, but that specific evidence of damage must be submitted. Smelting is a legal business and a smelter cannot be presumed to be a nuisance.

DREDGING is about to be the target of another investigation, this time by the Anti-Debris Committee of Sutter county. The members of the committee "have a suspicion," according to the report, that the dredges in the Oroville district are accountable for the muddy condition of the Feather river. We have a suspicion that the cause of this muddy condition of the Feather river is the same as that for most other rivers in the country at this season of the year.

AN attractive and useful little magazine, called *The Anode,* has just made its debut at the Anaconda Copper Mining Company. The publication will appear monthly under the auspices of the Bureau of Safety of this Company and will be devoted to the furthering of the 'Safety First' movement at the mines and plant of the Anaconda company. The first issue is devoted largely to the publication of information concerning the work which is being undertaken by the Company for the prevention of accidents; later issues will contain articles of general interest to the employees and items of news regarding the operations of the mines and plants. As the object of all the Company's various activities is the production of anodes for shipment to the electrolytic refinery, so it is planned that *The Anode* will voice the work of this great Company toward furthering the 'Safety First' movement.

REFERENDUM vote of the Miami Miners' Union on the demand for the restoration of the old wage scale, which was $3.75 per day, as against the 10 per cent reduction which went into effect last August, resulted in a decision to quit work until the demands of the union have been met. The properties affected are the Inspiration and Miami mines and concentrators, and the International smelter. The wages at present are regulated by the copper producers of the state according to the condition of the copper market. This method, in view of the general depression in copper since last August and the many difficulties attendant upon keeping the mines in operation, would seem equitable. The Inspiration company, while not in the producing stage, has conformed to this scale, and it will be recalled that twice in 1912 the companies affected voluntarily raised the wages of their employees in accord with the rise in copper at that time. The present strike is lamentable and it would seem that a more opportune time could have been selected for the presentation of the grievances claimed.

CRIPPLE CREEK is justly elated over the discovery in the Cresson Consolidated mine of a body of rich ore, the total value of which is estimated at from $1,000,000 to $6,000,000. It will be some time before definite figures are known, but at least one of the great bodies of high-grade ore, such as originally put Cripple Creek on the map, has again been found. Naturally this raises hopes of others, and probably no former Cripple Creek miner but can call to mind ground he would like to have explored. Despite the enormous amount of work that has been done in the district, there are many blocks of ground uncut large enough to contain more than one such bonanza orebody. The Cresson itself is in territory long passed over as unpromising, but the persistent work of Mr. Charles Roloffs and his associates resulted in an extremely profitable mine there long before the present bonanza orebody was found. No wonder that the hotels are crowded and that the lobby of the National has regained its old-time popularity. A veritable mining boom is on, and visitors are warned to engage rooms in advance. We are glad to say, with some personal knowledge of the district, that the opportunities for really finding ore are, in our judgment, excellent; much better than in many a 'new' district that has attracted even more attention.

TUBE-MILL PEBBLES as used in our modern milling plants have come to be an item of considerable importance in the economic conduct of this work, and it is therefore with pleasure that we print this week a detailed study of this problem at Tonopah by Mr. Jay A. Carpenter, of the West End company. It is peculiar that tube-mill operators throughout the world have depended to a greater or less extent upon Europe as a source of supply, the pebbles found near the plants being almost invariably of such an inferior quality that no economy was possible by their use even with the high freight charges which add materially to the cost of the

European product. There has been considerable discussion as to the use of ore in place of flints in tube-milling, but the consensus of opinion would seem to be against this practice. Rough pieces of ore have comparatively little crushing surface, and a loss in the efficiency of the mill and power consumption is inevitable until these pieces are worn into rounded shapes. Steel balls have also been tried, but because of their excessive weight and the consequent increase in power requirements, amounting to from three to four times that required by a charge of flints, they have generally proved unsatisfactory. This type of grinding has, however, proved the proper medium in ball mills, which take a three-inch feed and where a heavy rolling action takes place. Thus in the Marcy mill, steel balls are used where the purpose of the mill is to reduce two to four-inch ore to 10 mesh. The objections to the use of steel balls in tube-mills are discussed in detail by Mr. Carpenter. The discovery of a deposit of chalcedony near Manhattan, Nevada, from which artificial pebbles of a good quality can be produced at a reasonable cost may help to solve the local pebble problem, and the results of the experimental work at the West End mill on pebbles from this deposit are of interest.

RECONSTRUCTION IN MEXICO

Recent developments in the Mexican situation are far from satisfactory, and prospects for peace of a lasting character appear to be more remote than a few weeks ago when Carranza made a hasty departure from Mexico City and Eulalie Gutierrez was made provisional president, with Francisco Villa as his sponsor. With Huerta out of the way and Carranza in flight, the Constitutionalist, or what has come to be called the Conventionist cause since the Aguascalientes meeting, appeared to be so much in the ascendancy that a feeling of optimism was general. However, things do not happen in Mexico according to rule or prophets, and the *jefes politicos* of today are the *destierros* of tomorrow.

Gutierrez as provisional president is no more, having with the many Diaz successors passed into the limbo of a soon forgotten past, and General Garza, his successor, has commandeered the police force of Mexico City for military purposes and the establishment of some semblance of authority in the Federal District. Just at present there is a question as to whether Gutierrez has abandoned all claims to the provisional presidency or has gone to Pachuca with a part of his cabinet to establish a government in defiance of the Conventionalist authority in Mexico City. With Carranza and his constituents holding Vera Cruz, Gutierrez and a reported force of 5000 men at Pachuca, and General Garza with Villa's support holding Mexico City, the political arena of Mexico takes on the semblance of a three-ring circus with the Conventionists still the centre of attraction. The pending severance of friendly relationship between Villa and Zapata adds another difficulty to the situation, and our hopes for a speedy solution of the many problems which Mexico is facing may be given a further setback because of this anticipated controversy. Just what the solution will be is in no way apparent at the present time, but if we may conjecture the future from what has been the history of this tempestuous country, a return to peace can only be expected through the subjugation of the minority by force of arms, or with help from the outside in the form of American intervention. As this latter course is, at present, out of the question and in all probability will continue to be so, we can but look to the Conventionist element represented by those who fought for the Constitutionalist cause, for the re-establishment of peace.

The difficulties in the way of reconstruction, however, are numerous, and to bring a political plan which is representative of the wishes of the majority out of the present embroglio, and to enforce such a plan, is a task which we hope the Mexican people will work out for themselves. They have brought order out of chaos in the past, and while many see but little reason to believe that they will be able to do so again, the outlook is not without hope, as some would contend. The triumph of the Constitutionalist arms throughout northern and central Mexico while fighting in support of the 'Plan of San Luis Potosi' and the subsequent establishment of peace and order throughout this vast territory, with the exception of a small area in the state of Sonora, would tend to prove that the great majority of the Mexican people throughout this territory are sympathetic with and supporters of the proposed democratic rule and governmental reforms urged by the Constitutionalists. They have succeeded in expelling from this northern country the old federal authority as represented by the followers of Porfirio Diaz and the opponents of Francisco Madero. This Constitutionalist element at present is in command of the political situation in Mexico as far south as the national capital. The northern country so held is free from trouble, and with a restoration of confidence, improved labor conditions, and better transportation facilities, the mining industry should make rapid progress.

The end, however, is not in sight, as personal jealousies and political intrigue among the Constitutionalist or Conventionalist chiefs have resulted in the development of factions in the ranks, and now that the cause has been won, and the last vestige of *cientifico* rule eliminated, the question as to who is best qualified and most able to act as the chief executive is being decided in true Mexican fashion. It is to be regretted that Mexicans can not or will not settle such controversies at the polls, and that he who holds the presidency must establish his place by force of arms. Carranza has failed, Gutierrez has abdicated, and Garza we can but hope will hold office long enough to ascertain the will of the majority and peacefully accede to an executive who, with the Constitutionalist cause at heart and the Constitutionalist army to maintain his position, will rebuild the ruins of Porfirian Mexico and establish a lasting and nation wide peace.

THE COPPER PRODUCERS' ASSOCIATION

On January 13 the American Copper Producers' Association, of which Messrs. John D. Ryan, Rodolphe L. Agassiz, Joseph Clendenin, and James McLean were the executive committee, unanimously voted to discontinue its organization. It was formed five years ago for the purpose of compiling complete statistics as to production, refinery output, and exports of copper in this country, and the data thus prepared were given out to the public in the form of a table on the eighth day of each month. The cost of this work was distributed over the participating companies. Even from the beginning the plan was opposed by some of the producers, and as time went by, the opposition became stronger. It must be admitted that in some ways the arrangement was an anomalous one. The figures were prepared by the producers at their own expense, but the chief benefit of them was to the consumers. If the consumers had prepared a similar set of figures, showing the stocks of copper which they had on hand, the benefit would have been reciprocal, and a mutually satisfactory arrangement might have been arrived at. As it was, although the fact that these figures were prepared under the direction of Mr. L. C. Graton, now professor of economic geology at Harvard University, might have been taken as a sufficient guarantee of their integrity, it was perhaps only human nature that many of the consumers regarded with suspicion figures prepared for their benefit by the producers. Apparent ground for this belief was afforded by the fact that the export figures for each month as reported by the Association did not always correspond with the figures reported by the Bureau of Foreign and Domestic Commerce. As a matter of fact, the figures of the Association were the more reliable, though discrepancies resulted from the difference in the method of reporting the two sets.

Copper for export is, of course, sold some time in advance of when it is actually shipped. When the selling agency places the copper at the refinery on the lighter which delivers it to the ship, it considers its copper as exported, and so reports it. When the shipping company has completed the loading of a ship it takes the ship's manifest to the customs house, certifies to its accuracy, the necessary papers are executed and returned to the captain of the ship, and the ship sails as soon thereafter as practicable. When the manifests are passed upon, or the 'customs cleared' as the technical expression is, the figures as to the contents of the ship are turned over to the Bureau of Foreign and Domestic Commerce, and are duly reported by it as exports. It is obvious that whenever considerable quanties are being exported about the end of the month, total figures arrived at in two different ways would show quite a wide difference. The Bureau cannot guarantee the accuracy of its figures, since it merely reports the data given in the ship's manifest, and the customs service does not investigate these, since there are no duties on exports. There is no reason why the shipping company should report erroneous figures, but if it did there would be no means of checking them. The Producers' Association, on the other hand, knew exactly the quantities exported, since the buyer and seller have to agree on the weights involved.

Cessation of the publication of these figures is regrettable, for, although the producers had little to gain from them, accurate statistics in regard to anything are always helpful. It is true that brokers made use of them in their operations in the share market, but brokers are certain to carry on their operations, anyway, and it can scarcely be more objectionable to have them base their market strategy on accurate information than upon vague surmise. Looked at from another aspect, the disbanding of the Association appears like an opportunity lost. 'Many hands make light work,' the old aphorism says, and a group can always perform services for the general good which individuals are either unable or unwilling to undertake alone. The benefits of concerted action are seen in the extremely capable way in which the critical situation arising as a result of the war has been handled. In 1913 we sold to Germany nearly $75,000,000 of copper. Now that market is entirely cut off and it requires no great exercise of the imagination to perceive how such an abrupt dislocation of commercial relations might have brought ruin to many people engaged in the copper industry; an outcome which has been happily avoided.

As pointed out in these columns some time ago, the increase in our domestic output of aluminum, which is about to become effective, will presumably cause a decrease in the price of that metal. Aluminum is a possible competitor of copper in the electrical field, which absorbs nearly 70 per cent of the domestic consumption of copper, and a long distance transmission line recently constructed of aluminum in California is the equivalent of some ten or twelve million pounds of copper which failed to secure that market. If aluminum rules at a less price during the next decade, this competition will be accentuated, at a time when several large new sources of copper are becoming available. The Chile Copper Company alone expects to begin turning out a half million pounds of copper per day by April or May; the Inspiration and the Ajo mines will produce large quantities of new copper, while the leaching plants of the Anaconda, Utah Copper, and many other mines will put them in a position to largely increase their production. The companies have invested tremendous sums in increasing their output and lowering operating costs; it would seem good business to spend moderate sums at least stimulating consumption and thereby assuring that the selling price will remain at a level which permits satisfactory operating profits on these investments. We venture to assert the belief that it would have been good policy to keep the Copper Producers' Association alive, and divert its funds to maintaining a staff of commercial research investigators, who might develop new uses for copper in the manufacturing industry, and stimulate increases in its use for present purposes.

California Petroleum in 1914

By R. P. McLAUGHLIN

California produced more petroleum in 1914 than in any previous year, more than any single state has ever produced in one year, and about 40% of the total yield of the United States. The amount was about 104,033,000 bbl., valued at about $48,833,000. No entirely new fields were discovered. Production exceeded consumption every month of the year except April, which is reported to have shown a slight deficit. The total excess production, which went into storage, was about 7,000,000 bbl. Activity in drilling went cheerfully on, even in the face of overproduction and prices that are too low to return adequate profit to the producer. Even the European war, which directly affected the market for oil, failed to deter some operators from drilling new wells. Words are not at hand to describe adequately a class of men who conduct business in such a fashion. It is but fair to state that an antiquated system of leases, which require the drilling of wells whether or not they are needed, accounts for some of the wasteful development. At some time an enlightened public will doubtless forbid such a ruthless waste of material, which is limited in total amount. There were about 420 wells completed during the year. As this is the smallest number for six years past, and as the annual production has still steadily increased during that time, it is clear that development must be still further curtailed. About half of the new wells were drilled in the Midway-Sunset field. The Lost Hills and the Whitier-Fullerton fields followed next in order of activity.

Production

The condition of the various fields is indicated by the following table of approximate figures, based on nearly complete returns:

Field.	Production 1914, barrels.	Producing or completed wells.	Proved land, acres.
Coalinga	15,800,000	945	14,100
Kern River	7,073,000	1,690	6,450
McKittrick	3,865,000	278	895
Midway-Sunset	50,550,000	1,420	37,800
Lost Hills	4,855,000	231	2,620
Los Angeles	2,500,000	710	1,460
Whittier-Fullerton	14,100,000	568	3,010
Ventura	935,000	364	1,600
Santa Maria	4,355,000	225	4,470
Total	104,033,000	6,431	72,405

Collectors of oil statistics seem always to be satisfied with statement of gross amount of oil or numbers of wells. Frequently these figures are about as useful to the business man as a list showing exactly the number of nails in his office floor would be. When the price of oil varies from 35c. to $1 per barrel, depending upon its gravity, it seems strange none of the statistics published by marketing companies show anything as to amounts of various grades produced or stored. Cost of production and financial results are seldom dealt with in statistical accounts. With such common omissions of useful matter it may not be necessary to apologize for here presenting some original 1913 figures in a summary of the year 1914. The figures are from *Bulletin* 69, California State Mining Bureau, which is at present in press. Financial and operating conditions have changed but little since the figures were compiled, and they probably show something of what may be expected for 1914.

Accuracy of Statistics

To those not familiar with the difficulty in gathering information on financial and operating conditions it may be well to state that the obtaining of absolutely accurate figures is an impossibility; however, several separate sources of information have here been consulted and the figures are believed to be fairly representative. Only producing companies (totaling 276) were considered. There are some 800 incorporated oil companies in the state, but many have never been active. Capital, as shown by the figures, is not definite, but the figures are intended to include all payments for stock. The cash column is probably fairly accurate, but that showing property is probably a great deal too large. Dividends, as shown, are certainly not overestimated. They roughly indicate the profitableness of the business, but it must be borne in mind that many prosperous concerns reinvest their profits without paying dividends, which probably explains the fact that prices and operating costs appear to vary so slightly between dividend and non-dividend companies. Price of oil, as shown by these figures, clearly demonstrates that only in exceptional cases is oil production profitable when less than 40c. per bbl. is received. Operating cost is here so tabulated as to bring out the operating difference between fields, in the column of cost per well per day. This method of comparing costs is the only way for an operator to determine whether costs are reasonable. A little thought given to the subject will show the absurdity of the customary quotation of costs at only per barrel produced. Two properties might be equally well managed, but if one had very productive wells and the other only small producers, cost figures per barrel would show only the difference in productiveness and not the difficulty of operation nor effectiveness of management. The operating cost does not here include such fixed charges as depreciation, taxes, or insurance, but does include the drilling of new wells and overhead charges, such as officers' salaries. These cost figures are only general, and the subject is more fully treated in *Bulletin* 69, California State Mining Bureau. Marketing companies'

statistics account for most of the figures listed as miscellaneous. Comparison of the dividends and capital with those of the producing companies indicates that there is nearly an equal division of profits between the two branches of the industry, and that larger profits would be wholly justifiable in view of the hazardous nature of the business.

was entirely in keeping with the evidence presented more than a year ago. The companies are directed to file rules and rates for carrying oil. The law is still subject to attack in the State Supreme Court, therefore, it may still be some time before definite action may be expected. What the final result will be upon the oil industry is highly problematical, but undoubtedly

FINANCIAL AND OPERATING CONDITIONS OF CALIFORNIA OILFIELDS, 1913

Among important features of the oil business during the year, the European war has, of course, been most prominent. For some time after hostilities began, San Francisco harbor contained many idle tankers under foreign flags, and even after this phase of trouble was eliminated many markets of fuel oil were destroyed, among them being the copper mines and smelters and the Chilean nitrate mines. Shipments of oil from the fields decreased about 15% after August. Another effect of the war was to suspend several large deals involving California oil properties. The largest transaction thus supended included the Union Oil Co. and the General Petroleum Co., which were under option to English investors. It is currently reported that the Union Oil option has been extended gratuitously. Construction of the Valley Pipe Line from Coalinga to Martinez has not been appreciably delayed by the war, which is particularly surprising as it is backed by the Dutch-Shell interests, whose headquarters are in Europe.

The decision of the Railroad Commission of California that, under the law, all the pipe-lines from the San Joaquin fields are common carriers was not unexpected, and some very interesting facts are about to become the property of the public.

Final decision has not been made by Congress or the U. S. Land Office as to who is to own and control considerable tracts of land in the Midway field claimed by the United States government. The Secretary of the Interior offers contracts to operators, on disputed land, who were drilling prior to October 3, 1910, or were producing prior to August 25, 1914. The contracts specify that patent to the land must be applied for and then the operator may dispose of the oil if one-eighth of the proceeds is deposited in a national bank, to be paid as royalty to the government in case the patent does not issue. The United States District Court did not sustain the presidential withdrawal of some 3,000,000 acres of land on September 27, 1909. There was a later withdrawal authorized by Congress, and upon it future disposal of lands by leasing must rest, and there are close questions of title, where claimants to patent had done some work before the withdrawal. Litigation over oil lands, held under grants from the Government to railroads, indicate that the exception or

reservation of mineral lands in such grants is invalid. Oil has also been decided to be a mineral in the legal sense.

Water damage has been the subject of considerable investigation during the past year. At Coalinga many companies are successfully operating under an agreement to arbitrate differences as to damage from water. In the Midway-Sunset field an association of operators gathers information and advises owners of wells as to the best method of shutting off water. Strenuous attempts will be made this year to have a state law which will enable operators to act to a better advantage.

The Independent Oil Producers' Agency has had a large staff of engineers appraising its property. The Agency is composed of about 165 companies, united, under agreement, to market their product. Most of the companies are situated in the San Joaquin fields, and produce heavy oil. The organization is unique in that each company has an equal number of votes with every other in the direction of business. The appraisal is said to be the first step toward forming a single corporation. Such an effort will be watched with interest, because the Associated Oil Co. had a similar origin with results that have been unsatisfactory to the original stockholders.

Large Wells

Many large wells were brought in during the year, and enumeration of them would be tiresome here. One of the most noted was that of the Lakeview No. 2 Co. in the Midway-Sunset field. It came in during May at the rate of possibly 25,000 bbl. per day, and during the next five months produced about 3,000,000 bbl. of oil. The well was so large and unruly that it caused financial loss to its owners, and will doubtless damage much of the surrounding territory with water. Accounts from reliable sources indicate that the owners were almost criminally ignorant or careless during the drilling operations and entered the oil sand without knowing the true depth of their own well. If such is the true state of affairs, they certainly merit scant sympathy, and undoubtedly such procedure is far from uncommon. In the Whittier-Fullerton field, remarkably productive wells have been brought in, where one sees orange trees uprooted to make room for the drilling rigs, even though the oil is not needed now and some of the operators will lose money by their activity.

An important advance has recently been made in extracting gasoline from natural gas. More than a dozen compressing and refrigerating plants are now in operation, with an estimated daily production of possibly 20,000 gal. Gasoline prices are the lowest in several years. The outlook for 1915 is not particularly encouraging. There will undoubtedly be the same stupendous production, wasteful methods, and inadequate profits to producers. Prophecy as to when all interests will cooperate, either with or without governmental aid, would be extremely hazardous, although the time is surely coming when such will be the case.

Electric Mine Locomotives

By E. B. WAGNER

*The electric mine locomotive consists of several main parts. The electric power is carried down the trolley pole by an insulated copper cable. One end of this is connected to the metal frame that supports the wheel and the other end is connected to the circuit breaker, which acts similar to a safety valve in a steam line. This circuit-breaker is one particular type of automatic switch which opens the circuit when the load on the locomotive becomes too great. From the circuit-breaker the electric power is taken to the controller or 'throttle' of the locomotive. In the same case with the controller is the reverse lever. This is so arranged that besides changing the direction of the locomotive, it gives two speeds in both the forward and reverse directions of running. These are called 'series' or slow-speed position, which should always be used for starting, and 'parallel' or high-speed position, which can be used, if desired, after the locomotive has reached its maximum speed, with the operating handle in the full 'on' position. The operating and reverse levers are interlocked so that the latter cannot be moved except when the former is in the 'off' position. The rheostat, which is connected to the controller, is 'cut in' and 'out' of the circuit by the movement of the operating lever. From the controller the electric power goes to the windings of the motors and from them to the frame of the locomotive and then to the rails.

On starting the locomotive, the reverse lever should be placed in the 'series' position, and the operating lever turned on, a notch at a time, allowing sufficient time between the movements of the lever handle for the locomotive to come up to speed. If the wheels commence to slip, throw the operating handle to the 'off' position, back up, sand the rails a little, and try again.

On stopping the locomotive, the operating lever should be turned to the 'off' position and the brake applied, gradually at first, and then with more force, being careful not to skid the wheels. The greatest braking effect is obtained when the brake is applied sufficiently strong to just not slip the wheels. When the wheels start to slide or skid, the braking effect is practically nothing. In case of accident to the brake rigging or the refusal of the brakes to work, the trip can generally be brought safely to the bottom of the grade by throwing out the circuit-breaker, putting the reverse lever in the reverse-parallel position, and throwing the operating handle to the full 'on' position. By so doing the two motors are connected in such a manner that one acts as a generator and the other as a motor. The retarding effect produced, though not enough to stop the trip, will allow it to descend the grade at a safe speed. This is a point with which every motorman should make himself familiar, as it is often of material importance.

*Abstract from *Employes' Magazine* of the Lehigh Valley Coal Company.

Ore Treatment at Cripple Creek: A Review

By P. HENRY ARGALL

*In reviewing the metallurgical conditions existing in the Cripple Creek district at the close of 1914, and studying the progress of the past 20 years, it becomes apparent to the most casual observer that the metallurgical problems exemplified by sulpho-telluride ores have been most successfully solved. The large mills are handling ores of from $2.50 up to $4 per ton, obtaining from 70 to 80% extraction thereon, and are earning a profit of from 50c. to $1 per ton when handling 8000 tons of dump rock per month, or over. Six years ago, ore of this grade was considered worthless, and few metallurgists ever thought that this material would be worked, much less did they foresee the day when 1000 tons of such ore would be milled every 24 hours within half a mile of the town of Victor.

PORTLAND MILL.

It is interesting to remember the history of the milling of Cripple Creek ores, especially now, when nothing remains of the early-day mills but blackened foundations and greater or lesser piles of tailing, and when the Florence & Cripple Creek railway, the first ore outlet of the early days, is about to be turned into an automobile highway.

Stamp-milling and amalgamation, for many years the recognized mode of treating gold quartz, was first tried and but a brief experience sufficed to demonstrate the inefficiency of this process to deal with the free 'mustard' gold resulting from the oxidation of calaverite, on account of the difficulty of amalgamation due to a tarnish or covering supposed to be telluride of iron. During the years 1892 and 1893 there were, however, some 200 stamps at work in the district; the largest, the Rosebud and the Gold & Globe, having respectively 60 and 40 stamps at work. Percussion tables and blankets were later used, but even then low extraction resulted, and when unoxidized tellurides began to appear this process was entirely abandoned.

Smelting has been immediately recognized as the proper method of treatment for the rich ore, and from the beginning shipments of such ore went to Pueblo and Denver. At the present time the smelters continue to receive the rich ore, treating approximately 8½% of the ore shipped out of the district.

The first cyanide mill was the Brodie, erected about 1892 at Mount City and operated for some time with varying degrees of success. This was long before the day of vacuum-filtration, and the early-day trouble at the Brodie was encountered when trying to leach the slime.

Chlorination was next tried, the first mill to use this process being the Lawrence, erected, I believe, by Edward Holden in 1893. In 1895 the Gillett mill was started, using the barrel chlorination process as adopted

*Abstract from *The Cripple Creek Times'* 23rd annual review.

from that in use in the Black Hills in South Dakota, and operated for a year or so with different results.

In 1894, with the completion of the narrow-gage Florence & Cripple Creek railway to Florence, the Metallic Extraction Works, using cyanide, was constructed, and operation commenced early in 1895. Other mills soon followed, and Florence was for some years the milling centre. Later, with the completion of the Midland Terminal and Short Line standard-gage railways to Colorado Springs, Colorado City, with the Standard and Philadelphia mills, became a milling centre, and the United States Reduction & Refining Co. began to control the industry. This Company took over the Metallic Extraction and Union plants at Florence, closed the Metallic, and thus left chlorination the dominating process. Later still, the erection of the Golden Cycle cyanide mill at Colorado City, and the changing over of the Portland mill to the cyanide process, again put cyaniding in the lead.

The Metallic Extraction Works

Metallurgically considered, the Metallic Extraction Works was the one early-day enterprise designed to leave its mark permanently on the successful treatment of Cripple Creek ores. Here the roast-cyanide process was evolved, and from the experience gained here, Philip Argall designed and erected the Golden Cycle mill, and thus once more brought this process to the front. At the Metallic plant, also, concentration tests were made, and data obtained which later were to be used in the design of the Stratton's Independence mill, and figures were obtained on working cost and extraction which enabled Mr. Argall to tell his company, before even the foundations were started, that the Independence mill could treat, on a basis of 10,000 tons per month, the dump ore at a cost of $1.50 per ton and make an extraction of 70%. In the six years of its active life, the Metallic plant treated 500,000 tons of Cripple Creek ore, earned good dividends for its owners, and was in no small degree a factor in reducing treatment charges fully 50 per cent.

The close of the year 1911 saw the end of the chlorination process as a factor in the treatment of Cripple Creek ore, with the shutting down of the Standard plant and the changing of the Portland plant into one using cyanide.

In 1907 the problem of treating the low-grade sulphotelluride ore, ore of too low grade to pay transportation to the valley mills and treatment after its arrival there, in the district itself, was attacked. In April 1909 the Independence mill first unit of 5000 tons per month was started. In June 1910 the Portland company started its low-grade mill, and in October 1911 the Ajax mill was operating in a small way.

Of the various mills designed to treat Cripple Creek ore, the following table shows their processes, capacities, locations, and history:

Rosebud—100-ton, stamp-amalgamation, Cripple Creek; burned.
Gold & Globe—100-ton, stamp-amalgamation, Cripple Creek; burned.
Brodie—100-ton, roast-cyanide, Mound City; burned.
Lawrence—100-ton, chlorination, Lawrence; burned.
Gillett—100-ton, chlorination, Gillett; burned.
El Paso—150-ton, chlorination, Florence; burned.
National—100-ton, chlorination, Florence; dismantled.
Metallic—350-ton, roast-cyanide, Florence; dismantled.
Union—300-ton, chlorination, Florence; closed.
Dorcas—100-ton, roast-cyanide, Florence; burned.
Economic—300-ton, chlorination, Victor; burned.
Philadelphia—250-ton, chlorination, Colorado City; dismantled.
Standard—400-ton, chlorination, Colorado City; closed.
Portland—350-ton, roast-cyanide, Colorado City; at capacity.
Golden Cycle—1000-ton, roast-cyanide, Colorado City; at capacity.
New Portland—500-ton, cyanide-concentration, Victor; at capacity.
Independence—350-ton, cyanide-concentration, Victor; at capacity.
Ajax—150-ton, cyanide-concentration, Victor; about capacity.
Isabella—100-ton, straight cyanide, Isabella mine; one-half capacity.
Wild Horse—100-ton, straight cyanide, Midway; at capacity.
Jo Dandy—100-ton, straight cyanide, Jo Dandy mine; at capacity.
Anaconda—100-ton, straight cyanide, Anaconda; closed.
Trilby—100-ton, roast-cyanide, Trilby mine; closed.
Wishbone—100-ton, roast-cyanide, Spring gulch; burned.
Little Giant—100-ton, straight cyanide, Pony gulch; dismantled.
Homestake—50-ton, straight cyanide, Cripple Creek; closed.
Free Coinage—50-ton, cyanide-concentration, Altman; about capacity.
Dante—100-ton, straight cyanide, Dante mine; about capacity.
Vindicator—300-ton, screening plant, Independence; recently started.

Cripple Creek milling has had its amusing side, too, which one should not overlook in a review of this kind. One read, for instance, in *The Times* of October 5, 1909: "New machinery and tanks for the Stratton's Independence mill were delivered at the property yesterday, and it is learned that Manager Argall will build an addition to the already big plant for experimental purposes." A special to the *Rocky Mountain News* dated March 28, 1909, reads as follows: "Following the close-down of the Stratton's Independence mill Saturday, the employees of the plant have received their salary checks and been laid off. The only information obtainable from the management is that repairs in the roasting department were necessary. The mill, which was erected at a heavy expense, and which is said to have a capacity of 6500 tons per month, has never been run anywhere

near capacity. According to the assessment rolls, the last assessed valuation of the mill was $317,000, and since the last assessment about $100,000 has been spent in changes and improvements." Those two extracts are very interesting reading in connection with what we know of the Independence mill today.

In this review the next period is that of "secret processes." In *The Times'* write-up of the opening of the Portland mill, July 19, 1910, is the following: "In the agitating tanks the 'Portland process' chemical is added and is known to the millmen as 'goo-goo.' The 'pacifiers' having washed the cyanide solution from the slime, this solution is pumped to the surface again

day. This chemical process will undertake the treatment of low and high grade ores, it making no difference as to the quality or to the quantity of tellurium contained in the ores. By use of the chemical iodide, for which to make solution it is necessary that ¼ lb of this salt be added together with 2 lb. of cyanide and 2 lb. of cyanimide, the metallic tellurium is dissolved and recovered in the zinc dust."

Mr. Clancy claimed that the treatment cost in the Ajax mill would be $1.20. The Moore Filter Co., in an advertisement, claimed the total mill cost, on a 200-ton basis, to be well under 75c. per ton, and the actual loss of cyanide only 0.01 lb. per ton of ore treated.

STRATTON'S INDEPENDENCE, AJAX IN BACKGROUND.

to be used over and over again." I cannot recall that the Portland company ever made an official claim for a secret process, nor has Thomas B. Crowe, the metallurgist in charge of the Portland mill, ever published any explanation of either the 'goo-goo' or the 'pacifiers,' although the *Rocky Mountain News* of July 22, 1910, hazards a guess that the 'goo-goo' is cyanogen-iodide. Yet another expert of local reputation, noticing the conditions at the tops of the agitators, reached the conclusion that the secret 'goo-goo' was a combination of cyanide and yeast cake! In the issue of *The Times* of July 3, 1910, there is further enlightenment along chemical lines as follows: "The difference between bromide and cyanide is that the former is more soluble to gold, being an added salt. It is a very expensive chemical." But the 'Portland process' gradually died a painless death, and we went along in a humdrum mirthless way until the advent of the 'Clancy process' brought new humor to light. In *The Times* for October 25, 1911, was: "Something new of the Clancy process is learned each

Hence it is surprising to read in *The Times* of May 6, 1912: "The Colburn (Clancy) process undertook to do these things (eliminate tellurides without roasting or concentrating) by means of cyanimide and electrolysis, but an official statement from the people who have given the Clancy process a commercial trial is to the effect that the process needs perfecting." Concentrating tables speedily replaced iodide, cyanimide, and electrolysis, and the Ajax mill fell into the procession of successful operators.

But enough of the funny side. The big successful mills of the district today use no patent or secret process. The method worked out in the old Metallic Extraction Works at Florence, improved and introduced to the public at the Independence mill, has become the standard practice of the district. It is, in reality, a combination of previously well known processes adapted to fit the conditions. The sulpho-tellurides must be removed by either roasting or concentration, and since the cost of roasting is prohibitive, concentration was

adopted. The concentrate is sold to the smelters, while the remaining ore, freed from sulpho-telluride, is easily cyanided, and especially so when aided by bromo-cyanide. In brief, then, the successful method in use today on the low-grade sulpho-telluride ore embraces the following well defined steps:

1. Crushing the ore in cyanide solution, instead of water, in order that the cyanide may begin dissolving gold from the moment that reduction begins.

2. Removing the rebellious tellurides as completely as possible by a careful concentration process, conducted alike on slime and sand.

3. Either leaching the sand in ordinary vats to effect a further extraction and to wash out the remaining traces of cyanide, or simply washing the sand in its passage through a dewatering machine and allowing it to pass directly to the dump.

4. Treating the slime by air agitation with the addition of bromo-cyanide or other oxidizers, as and when required.

5. Precipitation of the gold from the cyanide solution either on zinc shaving or by the Merrill zinc-dust process, acid treating the precipitate to remove the zinc, and melting down into bars or shipping the crude precipitate to other refineries.

6. Selling the concentrate to the smelters. The important point here is that the smelter pays 10c. per unit for the iron in excess over the silica, thereby reducing the treatment charge materially on clean concentrate. Chemical processes do exist wherein it is possible to treat this concentrate at the mill and obtain 90% extraction; yet, considering the value of the iron content, which is lost in the chemical method, there is no process known today which can compete with smelting this product.

Future Milling

It is needless to dwell on the success which these low-grade mills have met, for it is ancient history to the residents of the district. With perhaps 150 men actively engaged in operating the mills, work is provided for fully six times that number of men in supplying the ore needed daily, as fully one-half of the tonnage treated is hoisted directly from the mines. There is work in sight for these mills for many years to come, and one may look upon them as giving assured life to the district for one or two decades, perhaps longer. Be it noted, however, that freight is of no import with the existing big mills; the ore is being treated on the ground.

During the past year there have been persistent rumors that one or other of the low-grade mills would be in a position to handle custom ore of $3 or $4 grade. While no official announcements have as yet been made, there is no doubt that something of the sort may be attempted at any time; but in order that the owners of dumps and low-grade ore in general should not become too enthusiastic, it is well to consider what it is possible to do with such ore on a custom basis. Assume a large dump of $3 ore, worthless to the owner without a mill. Having been sorted from the shipping ore, it may be said to have cost the owner nothing; it is, in fact, a by-product. With a mill on the ground it is worth what he can get out of it, less the cost of milling, thus:

Gross value of the ore per ton, $3.	
Extraction, 70%, per ton	$2.10
Milling cost, on a basis of 10,000 tons per month	1.50
Apparent profit per ton	$0.60
With 75% recovery	0.75

From which the cost of the mill must be returned during the life of the dump. Should this ore be shipped to a custom mill, the first charge is 50c. per ton freight, and on the assumption that the mine would expect something for the ore and the mill a small profit for milling it, it is evident that it would not be profitable. For custom milling I assume that the ore is of $4 grade, the probable extraction 75%, and I find as follows:

Milling cost, as above, per ton	$1.50
Railway freight in district	0.50
Loading and unloading cars	0.30
Metal loss, 25%	1.00
Working cost	$3.30
Apparent profit	0.70

Allowing 30c. per ton for profit on milling, the miner would receive 40c. per ton for his ore. Assume further that an aerial tram is built to handle this ore, the freight would then be cut to 20c. per ton, including amortization of a line 1½ miles long. In such a case the freight is cut 30c. per ton, and the profit on loading, transporting, and milling $4 ore becomes $1 per ton, exclusive of mill depreciation.

There is plenty of milling capacity in the district, and the construction of more large mills to handle sulpho-telluride ores would be a useless duplication of capital, and nothing less than a mill of 10,000 tons per month capacity can possibly handle such ores at a working cost of $1.50 per ton. What is needed is a cheap method of transportation to deliver the low-grade ore to the existing mills at, say, 10 to 20c. per ton, depending on the distance between mine and mill.

The year has been a most prosperous one for the district as a whole (980,239 tons of ore yielded $13,551,932, and dividends distributed, $3,128,685), and the part of this prosperity due to the low-grade mills has been neither inconspicuous nor underestimated.

Metals and ores exported from New South Wales during the first nine months of 1914 were as follows: Silver in bars and matte, 2,017,043 oz.; silver-lead bullion and concentrate, 283,315 tons, worth £2,525,357; lead in matte, 18,152 tons, worth £264,701; zinc concentrate, 345,167 tons, worth £977,126; copper in bars, ore and matte, 15,743 tons, worth £912,259; tin, 2151 tons, worth £253,370; and coal, 4,587,586 tons, worth £2,474,451. The total value was £7,628,671. Gold produced in 11 months was 108,892 oz., a decrease of 27,331 oz. compared with that period of 1913.

Danish Tube-Mill Pebbles and Substitutes

By JAY A. CARPENTER

Since the advent of the tube-mill for fine grinding, the Danish pebble has been the main grinding medium. The reason for this is that these pebbles are extremely hard, tough, nearly spherical, and the cost of production is limited to the cost of gathering them from the seashore, and then sizing and grading them for shipment. The cost of such flints, sacked ready for export from Denmark, is about $11 per long ton. The true Danish flint is remarkably homogeneous, and free from all cleavage planes or lines of weakness. On being fractured, the faces are sharp and irregular, and vary in color from a brownish black to a jet black. Occasionally the faces show irregular patches, a brown to gray color, which, while softer are apparently an integral part of the pebble.

The pebbles, from 1 to 7 in. diameter, are divided into about eight sizes, from size 0, 1 to 1½ in., to size 7, 4¾ to 7 in. diameter. The sizes most in demand are No. 3, 2⅜ to 3¼ in.; No. 4, 3⅛ to 3¾ in., and No. 5, 3½ to 4 in. These are sorted into different grades, varying from the best spherical or 'special hand picked' pebbles to the culls. This grade has not been given much attention by the millman, consequently most pebbles are purchased on the specification of size only, without reference to grade.

While the Danish pebble sells around $11 per ton ready for export, the price quoted by dealers *ex* steamer at New York is about $15, and the price delivered to the railroad station of the mines varies greatly with their situation, being in the case of Tonopah about $35 per ton. The same pebbles, upon reaching the mills at Manhattan and Round Mountain, 45 miles and 72 miles, respectively, from Tonopah by wagon road, cost $55 and $62.50 delivered. This nearly places the homely Danish flint in the class of its more fortunately colored brothers, the amethyst and opal.

Quantity of Pebbles

The quantity of pebbles used per ton of ore depends mainly on the hardness of the ore, the coarseness of the sand product fed to the tube-mills, and the fineness to which it is to be ground. At the West End mill, during the year 1913-14, the ore was crushed through battery screens with 0.19 to 0.27-in. openings, and the final discharge from the tube-mill circuit was 80% – 200 mesh. The ore is a hard quartz, not tough, but breaking into sharp fragments. The consumption of pebbles per ton of ore milled was 7.1 lb., varying from 4.82 lb. during one month to 8.73 lb. in another month. The higher limits were with the coarsest screens or with French pebbles. At $34 per short ton, this gives an average cost of 12.1c. per ton for pebbles. This is a high figure due to the coarse crushing in the batteries, and to heavy pebble loads in the tube-mills. The pebble consumption at three other mills in the district, all using finer screens, is 4.2 lb., 4.4 lb., and 4.7 lb., respectively, giving a cost from 7.1 to 8c. per ton of ore. At the Goldfield Consolidated mill the consumption of pebbles is about 4 lb. per ton, and the amount used in 1913 was approximately 660 tons. These figures show that the Danish pebble is an important item of cost in milling, and is a large tonnage item in the freight of a milling district like Tonopah.

It is primarily this cost per ton of ore for Danish pebbles that makes the millman interested in substitutes. It is also the carload substitution of French pebbles at Danish prices, and the receipt of inferior grades of Danish pebbles that sharpens his interest. There is an open question if the Danish supply can meet the demand coming from the increased number of tube-mills installed, and the increasing coarseness of feed to them. At least an extra cost or a decrease in grade can be expected. At the present time it is questionable whether the quantity exported will be seriously affected by the war. Prices soared in the early fall, but are nearly normal again with, however, the supply rather limited.

French Pebbles

A substitute for the Danish pebble in common use is the French pebble. This pebble on the exterior has much the appearance of the Danish article, and is as free from fracture planes; but on fracture its color is light brown to gray, in contrast to the dark brown to jet black of the Danish pebble. While pebble dealers may argue that Nature would not be mean enough to toss up a softer article to the Frenchman, the millman who compares pebble consumption knows it for a fact, even if the pebbles come to him under a Danish bill of lading, or with numbers on the sacks instead of letters.

The cost of French pebbles ready for export is considerably under the Danish, but delivered at Tonopah with the same high transportation charges added to each, the French is but little cheaper, and wearing faster, due, I presume, to being somewhat softer, its cost per ton of ore ground is higher. Where transportation is not such an element in the cost, the French pebble might give an equal or lower cost per ton.

The Newfoundland pebble has a limited use. This pebble is hard enough, but in those received at Tonopah there were distinct parallel fractures or bedding lines across them, along which they would fracture when broken. The reject from the tube-mills showed that this action took place to some extent in the mill, making their use uneconomical in comparison with the Danish pebble.

The substitute most commonly in use is that of pieces of mine ore. Primarily the great advantage of this is the low cost of the material and the saving of the purchase price of the Danish pebbles. Even if the ore only

carries metal equal to the cost of milling, it more than pays its own way in the subsequent steps of milling. On the Rand, according to 'Rand Metallurgical Practice,' the mine ore has entirely supplanted the imported pebble. This in spite of the fact that on a test run of one month, as recorded in the *Journal* of the Chemical, Metallurgical and Mining Society of South Africa, with similar mills, it required 171.5 tons of banket against 10 tons of Danish pebbles. The quantity fed to a mill per day is from 5 to 10 tons, or an average of 8 tons. This is 60% of the normal load of the mill. This figure is quite impressive of tonnage to those American operators who must rely on a small variation of meter reading to check up a failure to add the daily pebbles. This tonnage added to the mills during the year makes an addition of approximately 2½ to 3%, at the same or lower grinding costs.

The adoption of the banket for this purpose by all the mills is conclusive proof of the saving made over Danish pebbles. Although, in the test referred to above, the mill filled with banket gave slightly better grinding than the one filled with Danish pebbles, others cannot have agreed with this, as Alfred James, in his annual review[1] of 1913, states that authentic tests are still to be made to prove that the loss in grinding efficiency does not offset the saving in pebble expenses. Since it is generally conceded that a large portion of the grinding in the tube-mill, especially to my mind, extreme fine grinding is done by the rolling and sliding action of the pebbles, the rectangular edges on the banket must be a detriment to the best work possible. These edges may soon become rounded off, but in so doing a great deal of oversize material is introduced into the mill, being below 1½ to 1 in., which size material is spoken of in 'Rand Metallurgical Practice' as "of no further use for crushing purposes, and during this period it occupies valuable space—and arrangements should be made to remove them." In the extreme case of a square being reduced to a sphere the loss of volume is nearly 50%, and the oversize added to the mill would equal the volume of the pebble formed.

Cost of Power

Of the total cost of tube-milling, the cost of pebbles, though quite an item, is not the main one. Power is the heaviest charge, probably in most cases exceeding that of pebbles two to four times, and the cost of pebbles is probably about one-fourth to one-seventh of the total cost of tube-milling. If the use of ore as pebbles should entirely eliminate the cost of pebbles, it is evident that before adopting its use a careful study should be made to see if it impairs the efficiency of the other three-fourths or six-sevenths of the cost of tube-milling, for it is evident that the impairment would have to be very small to overbalance the saving made.

A. G. Quartana[2] gives data on the use of ore in place of pebbles in Mexican practice. In one instance the daily feed is 1600 kg. of mine ore, as equivalent to 250 kg. of Danish pebbles. He advocates a mixture of the two to avoid handling such large quantities of mine rock, and to furnish Danish pebbles to fill El Oro linings, for which purpose he says the mine rock is not adapted. He also commented on the destructive effect of the mine rock on smooth iron liners. Undoubtedly the use of mine ore or rock as a substitute for Danish pebbles will increase in use as the cost of pebbles increases. In the Tonopah district at the present time, the Tonopah Mining Co.'s mill is using mine rock or low-grade ore exclusively in its two tube-mills with good results.

Another substitute for Danish pebbles are rounded pebbles picked up from stream beds in the vicinity of the mills. These offer a marked advantage of cheapness, and an excellent spherical or rounded form. They have the disadvantage of being softer than Danish pebbles, as they are usually silicified igneous rocks. In a cyanide mill there would be a debit charge against them in the remainder of the plant, but on the contrary in a cement plant, I would presume they would add their quota to the cement. About four years ago flint pebbles from the Colorado river were used at the Tom Reed and Gold Road mills. Several of the cement mills in southern California use the pebbles of silicified igneous rocks found in their vicinity.

Steel Balls

Another substitute for the Danish pebble is a steel ball. Although the steel ball is in use in ball-mills for coarser crushing, it has found no application for fine crushing in tube-milling. The reason for this is probably that where the added weight in striking a blow or in crushing, weight is needed with coarser material, this very fact is against it in tube-milling, where grinding surface is vastly more important than weight. A steel ball would have nearly three times the weight, but no greater surface than a spherical pebble of equal diameter, and all added weight below the centre line of the tube-mill means greater power consumption. This statement is quite at variance with a circular letter recently issued by a reliable conveying machinery firm which has taken up the manufacture of steel balls for tube-milling. A test is quoted in which the capacity of a 5 by 22-ft. mill was increased from 14 bbl. of cement per hour to 23 bbl. by the use of 'manganoid' steel pebbles, and "power requirements not increased." If this be so, their use will become common. Undoubtedly these balls can be made harder than the Danish pebble, closer grained, tougher, and more spherical, which advantages should more than compensate for their greater first cost, especially in distant fields where transportation is the greatest item of final cost.

There might be raised an objection to the steel pebble on account of the metallic iron introduced into the pulp to be cyanided. Several years ago there was a strong prejudice against the cast iron liner as a substitute for silex on this same ground. Not so long ago, with a

[1] *Mining and Scientific Press*, January 3, 1914.
[2] *The Eng. & Min. Jour.*, May 20, 1911.

change of metallurgical engineers at a mill being constructed at a considerable distance from railroad, the new El Oro lining available was discarded on this assumption, and a hurry-up order for silex telegraphed out. Mills in the Tonopah district using smooth cast iron liners over long periods have never noted any harmful effect from this source. In one mill where the pulp was concentrated after tube-milling, the metallic streak of iron was quite noticeable on the final reconcentrating table, giving some idea of the quantity in the pulp. In this case it was shipped with the concentrate, but later, when concentration was discontinued, it went through to the filters with the pulp, as in the other mills. If this iron was acted on by the mill cyanide solutions, it should introduce appreciable quantities of ferrocyanide in the mill solutions. The regular and frequent tests of these solutions at the West End mill for impurities have never disclosed any ferrocyanide, in spite of the large amount of iron in the pulp, the high cyanide and alkali solutions, and the high heat and long agitation.

There is one drawback to experimenting with steel balls in tube-mills designed to carry pebble loads, that of placing too heavy a strain on the tube-mill heads and trunnions. W. A. Caldecott[3] gives the pebble load of a 5 by 22-ft. mill, 56 in. inside of liners, and filled to the centre line, as 9.88 tons. The weight of the pulp within the mill is about 4 tons, giving a total load of 13.88 tons. If steel balls of about three times the density of quartz were substituted, the pebble load would then be 29.64 tons, and the total load 33.64 tons, or 2.42 times as heavy. This load would subject the tube-mill to strains beyond which it was designed, and might exceed its factor of safety.

Artificially Rounded Flints

If, as the circular mentioned stated, the power requirement (interpreting it literally to mean the power requirement per ton of cement) was not increased, then the added weight of the steel pebbles must add wonderfully to the grinding efficiency of the mill. At least, the steel ball is worthy of more experimental work. It must be that large cement plants, having tons of reject steel balls from Lehigh-Fuller mills or ball-mills, have tried them out in tube-mills, but I know of no published data on the subject in the technical press.

Another possible substitute for the Danish pebble is an artificially rounded flint. This substitute is now being tried in the Tonopah district. Such a pebble will have limited application in tube-milling, due to the fact that there must be available a deposit of homogeneous flint, chalcedony, or onyx, and a consumption in the district large enough to justify a 'tumbling' plant.

Omer Maris, of Manhattan, found such a deposit near that place. The rock can be described as a banded and patchwork onyx, yet it has no tendency to break along the banded or patchwork lines, and all the various colored components seem to be of nearly equal hardness. Mr. Maris believed this rock could be used as a substitute for Danish pebbles, and has devoted all his time and energy to bringing this about. As the Danish pebble is worth $50 per short ton in Manhattan, the mill operators gave him hearty co-operation. The first experiments consisted of charging several tons of rough surface rock into the mills. The edges soon rounded on these rocks, and then they gave equal wear with the Danish pebble. After the Manhattan mills adopted the rock for pebble use, Mr. Maris began to mine the rock in order to get fresher material. Soon after this, enough rock was sent to the Belmont mill at Tonopah to charge a tube-mill and supply it with feed during a test. The net result was that the consumption of Manhattan rock was 6.44 lb. per ton of ore against 4.14 lb. of Danish, and its efficiency as a grinder, judged by the amount of minus 200 mesh in the discharge, was only 80% of the Danish. A small lot sent to the West End mill was charged into a mill, and the large amount of broken fragments in the discharge of the mill during the first day did not augur well for the rock, but several weeks later, on opening the mill, the size of the pebbles remaining bore testimony to their hardness.

Results at the West End

It was apparent that the rock must be made into a pebble before shipment, to save freight and to give it a better record for wear and efficiency. A tumbling barrel or mill was built for this purpose, and from the rectangular rock, after an hour or two of dry rolling, a fair pebble is produced. It is far from spherical, but all corners are rounded, and waste in the tube-mills is thus eliminated. This rounded pebble is now being tested in Tonopah mills and the Goldfield Consolidated at Goldfield.

The results at the West End mill have been quite favorable to the pebble. There are two 5 by 18-ft. tube-mills in the plant driven from a common pinion shaft at the same speed, and each taking the classified sands from 10 stamps with screens having 0.12-in. openings. No. 1 mill has smooth liners and No. 2 has Komata; the latter lining being credited with being more economical on pebbles. During August, 12,500 lb. of Danish pebbles was added to No. 1 mill. Beginning September 1, Manhattan pebbles only were added daily to the mill, totaling 11,640 lb. for the month. As the pebble load of the mill when carried at centre is about 8.1 tons, and the daily charge is about 400 lb., the average life of a pebble is 40 days. Calculating from this, the load should have been about one-half Manhattan on October 1. During October there was added 12,190 lb. of Manhattan pebbles, and when the mill was opened the load was at the centre line and all the pebbles except the smallest were Manhattan pebbles. During November there was added 13,490 lb., leaving the mill with a slightly higher load. Comparing the above months, it will be seen that the Manhattan pebble is practically equal, pound for pound, with the Danish pebble, as far as wear is concerned.

During November the load was entirely Manhattan

[3] *Mining and Scientific Press*, June 6, 1913.

pebbles, but different from charging the mill with all one sized pebbles, for by the method of adding them gradually there were all sizes of smooth worn pebbles in the mill down to those small enough to pass through the discharge screen. During November the fineness of the pulp at the discharge of the mill remained practically the same as during the preceding three months, being about 45% – 200 mesh.

In November No. 2 mill took 12,800 lb. of Danish pebbles. This gives a comparison of the Manhattan and Danish pebbles as follows: wear ratio, 1.05:1; cost per pound ratio, 0.95:1.73c.; cost per ton ground ratio, $1:$1.75, or a saving of 40% on pebble cost by Manhattan pebbles. To offset this gain is an occasional delay or stop due to irregularly shaped pebbles sticking in the tube-mill scoop.

While this pebble appears to be as efficient a grinder as the Danish pebble in the smooth-liner mill where a large share of the grinding is done by slippage, and the pebbles tend to wear flat, it is a question whether they would be as efficient in the Komata lined mill, where the pebbles are cascaded; the more nearly spherical the pebble the more efficient the grinding. They are being tried with this type of liner at other mills in the district.

These pebbles are delivered at Tonopah with a wagon haul of 40 miles at $19 per short ton. It is evident that at this price the Manhattan pebble has a marked advantage in price at Tonopah over the Danish, but with freight shipments from Tonopah toward coast points this advantage rapidly diminishes to a vanishing point, leaving this particular substitute for the Danish pebble to the limited field of local use.

The subject of the Danish pebble and its substitutes is an interesting one to the mill operator, and if many operators hold opinions different from those expressed above, they must remember that this article is based to a certain degree on personal opinion, since the literature and discussions on the subject are limited, which fault lies in their power to correct.

TRIBUTERS OR LESSEES at Kalgoorlie, Western Australia, mine a considerable tonnage of oxide and sulphide ores. The former is treated in a number of custom mills using stamps or Huntington mills; but the latter, since the Associated Northern dry-crushing, roasting, and cyaniding plant was dismantled after 10 years' run, has no suitable plant. The government was approached and asked to provide a mill, but in the meantime the metallurgical firm of Allsop & Don leased the Hainault mill of 40 stamps, Cobbe grinding pans, Wilfley concentrators, and sand, slime, and concentrate treatment processes, for the treatment of custom ore. The following charges are to be made for complete treatment of the sulphide ores supplied, 90% recovery being paid for: ore worth $15 per ton and under, $4.80 per ton; for each additional dollar up to $20, 25c. per ton extra; and for each additional dollar over $20 and up to $60, 12c. per ton. This gives a minimum of $4.80 and a maximum of $10.80 per ton. The government is granting the mill lessees a subsidy of $4800 to make necessary alterations to the plant. This should be a satisfactory arrangement, as the Hainault mill is complete. Thus the government at small expense aids a large number of miners, who otherwise would have difficulty in getting their ore properly treated.

Mining in the Belgian Congo

The following circular has been issued by the Union Minière, a subsidiary of Tanganyika Concessions, Ltd.:

"The estimated production of copper by the Union Minière du Haut Katanga for 1914 was 12,000 tons; for 1915, 25,000 tons; and for 1916, 40,000 tons. After the occupation of Brussels by the Germans, part of the Union Minière executive staff, including Mr. Velge, the secretary of that Company, was transferred from Brussels to the offices of the Tanganyika Concessions, Ltd., London, where legally constituted directors' meetings are now regularly held in conformity with article 16 of the articles of association of the Union Minière du Haut Katanga. The Company's smelting operations at Katanga have been kept running without interruption, although copper fell rapidly from £60 to £48 per ton, but has risen since, as will have been seen, to over £56 per ton. During the period that has elapsed since war started, and although considerable difficulties have been caused directly by the war, two furnaces have been kept in blast, producing 3730 tons of copper up to the end of November. The third furnace was blown in at the beginning of December in order to increase the output of copper, and, in view of the rising price of the metal, it is estimated that the total production for this year will therefore not be far short of the 12,000 tons anticipated. The copper produced from the beginning of the year up to the commencement of the war was realized at a price which shows a profit of approximately £20 per ton over the cost delivered in England. In spite of the adverse conditions affecting the metal market since the beginning of the war, the copper produced and landed in England since then has been sold at a price which shows a profit of over £10 per ton over the cost delivered in London. At the present price of copper a considerable increase in this profit will be secured, and as the price of copper is improving, the Company is now considering the immediate erection of two further blast-furnaces which have already arrived at Beira, on the east coast, and it is hoped that the Company will be able to erect these within a short period."

COKE-OVEN ACCIDENTS in 1913 were as follows, according to Albert H. Fay, of the U. S. Bureau of Mines: plants operating, 227; men employed, 24,345; killed, 46; seriously injured, 342; and slightly injured, 2172. The rate of fatalities was 1.89 per 1000 employed, against 1.72 in quarries and 2.06 at metal mines, surface only. There are over 100,000 ovens in 575 plants in the country. About 50% of the deaths were due to transportation systems.

Mining in Newfoundland

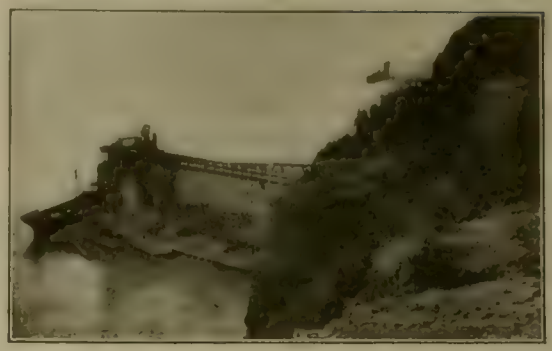
By AN OCCASIONAL CORRESPONDENT

Newfoundland, England's oldest colony, is rich in minerals. It is somewhat larger than Ireland; has a population of only a quarter of a million people, most of whom are fisherfolk living in the many bays far from railroads, and it is insular in fact as well as in reality. Ocean liners steam into the Gulf of St. Lawrence only a few miles from its wild-looking shore which John Cabot first saw in 1497; and it appears much the same now as then. In only a few places have serious efforts been made to develop the mineral wealth; and in still fewer have they been developed under successful management which understood conditions and possessed a sense of proportion. The colony is under a government of its own, separate from Canada, and politics are taken very seriously by the various factions, including the fishermen's union, the big merchants, the English interests, and others. It is a windy, rocky, barren country, with few railroads and almost as few wagon roads. The men available for labor live principally on tea and jam, and show the lack of a hearty meat diet; and the little stunted ponies they drive never haul over half a ton at a load.

On the other hand, the island is well situated for shipping to Canada, the United States, or Europe; it has an extensive coast line with plenty of good harbors, where coal can be brought by steamers or schooners from Sydney, Cape Breton, just across the Gulf of St. Lawrence; the summer climate is excellent for work; and the men can be hired cheaply, and are of 'white man' stock.

Newfoundland iron ore is well known in the markets of England, Germany, the maritime provinces, and the eastern states. It is a hard blocky hematite of about 50% iron, and well liked for furnace mixing; much of it occurs in blocks the size and shape of bricks —a peculiar freak of nature, but not inconvenient for mining. There are several seams of it interbedded with Cambrian sandstones and shales, and varying up to 30 ft. in thickness. The strata outcrop on Bell island in Conception bay, where for many years it was thought to be 'red sandstone,' and they dip at an angle of eight degrees under the ocean, down which incline 'slopes' have been driven for miles, mining being conducted under the sea.

IRON MINE ON BELL ISLAND.



IRON ORE LOADING PIERS, BELL ISLAND.

There are two large companies operating on Bell island (which contains 12 square miles), the Nova Scotia Steel & Coal Co., which purchased the original leases in 1893, and the Dominion Iron & Steel Co., which in 1898 paid the Nova Scotia company a million dollars for extensive surface and submarine tracts that the latter Company is now sorry it sold. Both companies ship ore to their own furnaces and steel works at Sydney, 400 miles away, where they also operate coal mines; and in addition the Nova Scotia company ships extensively to Middlesboro, England, to Rotterdam for German use, and to Philadelphia.

Bell island is described in the advertising pamphlet of the Nova Scotia Steel & Coke Co. as "set like a jewel amid heaving waters;" but for the most part it is a wind-swept, lonesome-looking bit of rock, seen to best advantage in summer. However, the cable-operated tramways across the island from the mines to deep anchorage, the ore-shipping piers, the ingenious stockpiling arrangements, the power house at the coal-unloading pier, and the general equipment are first class and of elaborate design. Between one thousand and two thousand men are employed in good times; in the shipping season of 1909 the Nova Scotia Steel & Coal Co. loaded nearly a hundred steamers varying up to 7500 tons capacity in an average loading time of three or four hours. The ore reserves under Conception bay are estimated to extend nearly to the northern shore, and will last at least a hundred years, beyond which it is scarcely worth while computing. It is stated that the attention of mining men was first directed to the Bell Island hematite through a fisherman sailing to St. Johns with some of the material in his boat as ballast. As an illustra-

tion of a peculiarity of the Newfoundlanders who do the mining, the management of one of the iron-mining companies on Bell island was threatened with a general strike when it attempted to do away with the 'mug-up' habit of the men, which consists in stopping work at 10:30 and at 4 o'clock to boil tea on the underground electric stove and eat a lunch (in addition to the regular dinner interval). This frequent lunching habit of the men is probably due to their subsisting on bread, tea, and jam in a climate so variable that most outdoor work has been uncertain and temporary.

Copper Deposits

'Up north' in Notre Dame bay, along a steep rugged shore, is a district long famous for copper ore. Since 1864, when mining was begun, copper ore to the value of $20,000,000 has been exported, and several of the English companies made very handsome profits, especially the Cape Copper Co., formerly of Tilt Cove, but now developing a new deposit 30 or 40 miles up the coast at Bay Verte. At one time metallurgists were brought over from Swansea, England, to operate a copper smelter at Tilt Cove, and considerable money was spent for several years in the effort to smelt the ore on the ground, but the attempt did not succeed, as the ore is more suitable for smelting when mixed with other varieties. Pyrite of a variety high in sulphur is common in the northern bays, and from Pilley's island in Notre Dame bay over $1,500,000 worth has been exported, although the mine is at present idle and full of water.

Among other minerals known to occur in Newfoundland are coal and petroleum, but lack of interest, roads, and proper management all have tended to discourage development. For instance, petroleum has been known to exist on the west coast, particularly at Parsons pond, for years. The last attempt to utilize it was by a British company which started several years ago with high expectations. Oil drillers from Pennsylvania were engaged, in order to get experienced men, and then the troubles began. So much difficulty was encountered from the machinery getting stuck, and so much difference of opinion resulted as to just where the drilling should be done, that several vague rumors are around as to "interference by American oil interests to keep down competition" and "action by the British government to conserve the oil resources for the navy." At any rate, the company became discouraged, and stopped work, although at least one small well was found. At other places on the west coast favorable looking beds of coal of good quality have been discovered and reported upon; and it seems strange that no one has attempted to do anything in a commercial way with such an important and basic commodity as coal situated in a country which imports coal, and close to the coast, where exporting to half the world would be easy. The Newfoundland government has been accused of discouraging too much interference in its insular affairs by outsiders; and it is true that wealthy St. Johns men, like the Reids (who built and operate the railroad), and various English interests, have tied up immense tracts of land for the sake of holding it; but on the other hand, many of the men in the government and business life of the island have overcome their insular prejudice and are anxious to help any new development of the colony's mining or industrial affairs. The prospecting laws are liberal, the mines regulation act is not unfair, and the workmen's compensation law is not a serious matter to a company of individuals starting mining operations in Newfoundland.

For instance, as to the crown lands act regarding mineral lands, any person can prospect upon public lands without first obtaining a license. A mining claim can be taken up by marking the mineral deposit by a discovery stake, and applying to the Crown Land Office at St. Johns for a license for one year, costing $11; the claim is one mile by one-half mile. During the year for which the license holds, a lease can be applied for, good for 99 years, costing $20 the first year, $30 per year for the next five years, $50 per year for the second five years, and $100 per year for the remainder of the term. Or, a grant in fee simple can be secured after expending, during the first five years, the sum of $6000 in mining operations on the claim. When a lease is applied for, the applicant is entitled to 50 acres of surface rights on his claim, and a right-of-way of a road out to the beach or main roads. The mines regulation act contains only such ordinary restrictions as those commonly incorporated for safety purposes.

Disadvantages of Mining

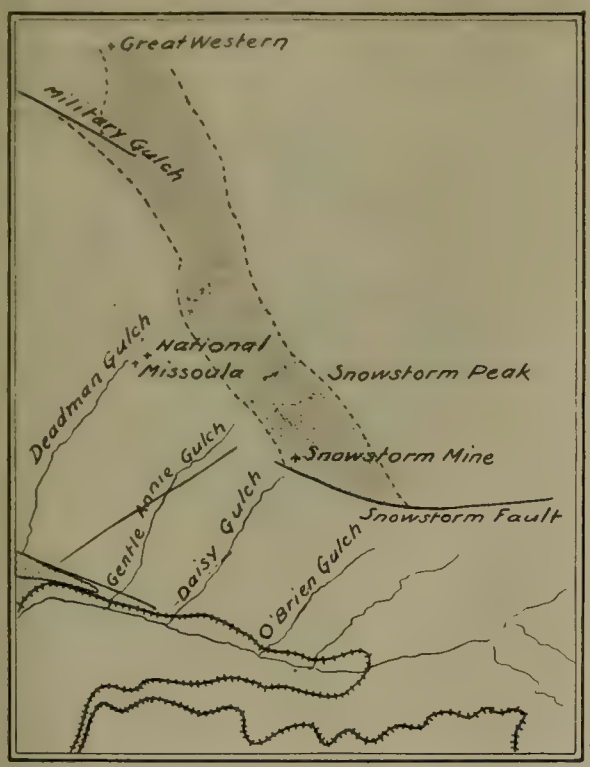
Some of the disadvantages of mining in Newfoundland are due to its isolation and the long time required for mails to come and go (although the railroad across the island has bettered these matters somewhat); the weather is very changeable, as is true of all islands, and the frequent storms during two-thirds of the year make outdoor work irregular, in spite of the fact that the winters are not particularly cold or snowy. 'Newfoundland fogs' are mostly at sea and not numerous on land. Up to a few years ago mining on several hundred miles of the coast (west, south, and northeast) was considerably hindered by French warships, due to France's claim that her rights to fish and dry the catch on those coasts gave her authority to prevent any developments which might injure fishing and drying. More than one hopeful mining man who has started operations on "the French shore" of Newfoundland has been amazed by a huge warship appearing off the coast opposite his prospect hole or development and being warned not to trespass on the rights of the French fishermen. He was told that he was "scaring the fish" by blasting and too much noise. But these matters, which were so long such a bone of contention between Britain and France, have at last been adjusted successfully, so that greater freedom exists for all those who care to brave the bleakness and solitude of the French shore in search of minerals and mineral substances.

The Copper Beds of the Coeur d'Alene

By GEORGE HUSTON

The so-called copper beds of the Coeur d'Alene have been the object of my study over a period of seven years. The areal geology was covered for seven miles in length by one mile wide. Observations were made underground all over the area to the extent of 65,000 ft. of tunnel, shaft, and open-cut work.

Mullan and Larson are the nearest towns to these beds, from which is derived the copper ore of the Snowstorm and National mines. A large amount of development is in progress along their strikes with a fair chance of bringing in more producers. The commercially mineralized beds consist of highly silicious pre-Cambrian quartzites occurring in what is known as the Granite Peak syncline, situated in the east-central portion of the Coeur d'Alene region. The syncline course or trend is nearly north-south for slightly more than half of the distance, after which it swings or swerves to a more east-west course. The upper half of the area north of Canyon creek is of minor importance. From this stream south and east, a distance of about 25,000 ft., the trend may be divided into two divisions according to the strike, the north division for 12,500 ft. and the south division for the same distance. The former stretches from a point just above the upper workings of the National mine to the workings of the Great Western group on Canyon creek. The south runs east-south from this point to the No. 3 adit level of the Snowstorm mine. The Granite Peak syncline is one of the most plainly marked structural features of the region. It is traceable seven miles and probably reaches a greater distance. The trough is filled with sedimentary rocks of the usual Coeur d'Alene series, in age downward, namely, the Wallace, St. Regis, and Revett formations. It contains no visible igneous rocks. Side pressure against the limbs has fractured a plane line down about the centre of the trend, on a scale sufficient to produce mashing and faulting with an overturn effect on the west limb. The pitch is south and the syncline is unsymmetrical.



MAP OF SYNCLINE SHOWING PRINCIPAL FAULT LINES AND AREA OF REVETT FORMATION.

At the junction of the two divisions the syncline swerves more to the east, the pressure effects being found in rocks of both limbs, agreeing with the strike. The wrenching effect has opened fissures across the brittle beds of the east limb, which are quartz filled. These show copper and galena in the immediate neighborhood of the impregnated beds, but the mineralization quickly dies out with distance and the fissures themselves fade away into branching veinlets. They are of no commercial value.

Revett Formation

Each formation, the Wallace, St. Regis, and Revett, contains a group of beds containing copper, but the first two are not profitable for reasons to be named. The Revett contains a group of beds from 20 to 60 ft. in thickness, impregnated with copper sufficient to make pay-ore at intervals. These beds lie in the first or top 350 ft. of the formation, and this holds good over the entire area. The transition from St. Regis to Revett is somewhat indeterminate, but recognition is possible within 50 ft. So plainly defined is the trend that an experienced observer can follow it on the surface, in its sinuosities and faulting, for the length of seven miles, knowing the position within convenient prospecting distance at any point.

The west limb of the syncline is practically barren, the east limb holds the copper beds, and these terminate on the dip into the centre plane of fracturing and faulting. The faulting, as noted, follows about the centre line of the trough, the Sonora fault on the Canyon Creek slope connecting through with the Snowstorm fault on the Mullan side. There is minor faulting which may influence the ore beds, between them and the Sonora fault. The plane line of the fault agrees with the course of the syncline. Looking from the lower end of the south division to the upper end of the north, the faults of horizontal throw are right-hand faults. The swing change in strike governs the throw direction, a fact

useful to the operator in finding lost copper beds.

Lateral pressure over a restricted area on the southeast end of the south division has elevated the syncline bottom, folding St. Regis strata against the Revett ore beds. This is seen on the No. 3 level of the Snowstorm mine. It cuts the ore strata off at about 4700 ft. above sea-level. The pressure effect dies out to the west, giving increased strata length with distance before reaching the fault again. A slight elevation apparently took place around the National mine near the strike change, and the ore beds enrich to the commercial stage again, although the difference allows the ore to go much deeper than at the Snowstorm. The elevation at the Snowstorm mine has given rise to an extensive fault on the east side of its holdings, displacing the beds evidently with a horizontal throw. It is traceable for a long distance. Undoubtedly, they continue east from this point, but I have not studied them.

The dips are flatter in the northern division and the strike more regular, although some movement and faulting is visible near the Great Western group on Canyon creek, but in lesser magnitude than around the Snowstorm and National mines. The dip in the south divisions are far the steepest, which, coupled with the movement, has had an important influence on the depth to which the ore will proceed, the kind of minerals, and the enrichment effect, also the oxidation.

The structural features of the Granite Peak syncline are ably dealt with in Prof. Paper 62, U. S. Geol. Survey, pp. 66-67, and admirably shown on the plate 2 map of the report.

The Copper Beds

As mentioned, there are three distinct occurrences of copper beds, one each in the Wallace, St. Regis, and Revett formations of the east syncline limb. The first two groups are in Wallace and St. Regis rocks, with a large amount of sericitic and other matter, which originally, no doubt, was sandstone or sandy shale, thin bedded, and affording very moderate opportunities for circulation of underground solutions. Infiltrations closed the pore space during the time of metamorphism. Subsequent movement due to pressure has not operated to release mineral, as the rocks smash into gouge, a condition antagonistic to free circulation. The principal copper mineral is chalcopyrite. Galena occurs, and rarely a little sphalerite. The rock carrying the minerals has almost the appearance of a hornstone, and the degree of impregnation is vastly less than with the Revett occurrence.

The copper beds in Revett are thicker strata, brittle, and composed entirely of quartzose matter plus the copper minerals. In crushing or under pressure, they have a tendency to break down like loaf sugar. This structure, favoring free circulation, explains the reason for this enrichment to commercial value. Along the seven miles observed, the Revett group originally contained copper in sulphide form of apparently one-fiftieth to one-tenth of one per cent per ton of rock. It was in intimate dissemination of chalcopyrite seemingly with the rock matrix. Silver to the extent of 2½ oz. or more to each 20 lb. of copper prevailed, with a very small amount of gold. Along a small portion, silicification proceeded to the degree of excluding the copper minerals, but the portion is insignificant and may be a secondary feature on the upper parts of the dip after the rock has been robbed of its copper content. Enrichment has occurred with change of a greater or less degree in the volume and kind of mineral, at intervals where favorable geologic conditions allow.

Copper Impregnation

The deposits are unique in that the nearest igneous rocks are miles away, and there are none whatever in the syncline. There is much to support the theory that the impregnation took place coincident with the metamorphism, the silicious and copper solutions traveling together to fill the pore space in the original sandstone, converting it into the present quartzite, with recurring intervals of pressure, crushing, and cementation.

Weathered quartzite from the Snowstorm mine outcrop shows typical coarse grains of quartz, around which were deposited the silica and copper cements. The rock suggests an early very open circulatory condition, with changes in copper minerals, made through breaking down under pressure. The latter would indicate that the change took place after the faulting and that originally the type of mineralization in the south division was similar to that in the north. The faulting movement steepened the dip, increased through this the concentrative effect, and gave copper minerals of greater content and density. What became of by-products will be noted later. Weathering of exposed strata contributed by sending the released mineral below the plane of the dip, being the easiest path of travel, as the mineralized strata were the weaker and were thus kept open.

The syncline fault I interpret as constituting a dam which held back the solutions, while faults across the strike assisted in checking the flow and thus caused deposition. The evidence is that cross-faults in combination with the dip are responsible for the areas of commercial enrichment. The source of the copper can only be conjectured.

The copper beds are normally very dry; in fact, the presence of water quickly robs them of the soluble minerals, transporting them elsewhere. Water is a bad sign for the prospector.

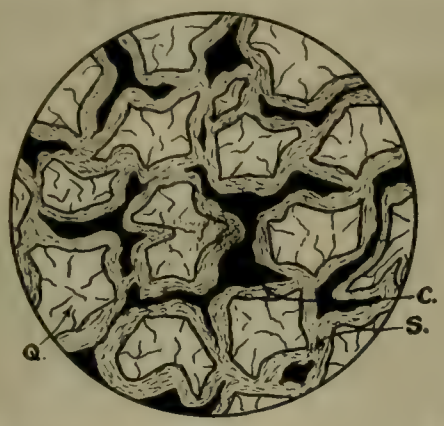
Chalcopyrite is seemingly the primary mineral. Chalcocite is a derived mineral, being found in all stages of formation and transition. Bornite is present. Pyrite is absent over the entire area, only one instance of its occurrence coming under observation, in the Snowstorm mine on an intermediate level, and even then not being in the copper beds proper. A horizontal throw had offset the beds to the north, and pyrite was found through a 30-ft. width containing galena on what would have been the continuation of the orebody. Fault action had smashed the rock to the south, and open spaces were

abundantly coated with pyro-morphite, the chlor-phosphate of lead. The iron oxide effect, so prominent in the upper and lower levels, over and under the occurrence were here notably absent.

Enrichment Evidence

Enrichment in this case may be defined as a change in minerals, resulting in a higher copper content with the casting aside of others. In the destruction of the primary ore and its change to the finished type, the by-products must be accounted for. This is possible in the Snowstorm mine. The discarded iron of the primary chalcopyrite is found as a hydrated oxide in the smashed rocks on the east side of the ore beds. Also these rocks show the effects of acidified water. The micrograph shows the occurrence of copper in quartzite at the Snowstorm property.

Chalcopyrite is almost absent from the Snowstorm



Q, QUARTZITE; C, CHALCOCITE; S, SILICIOUS CEMENT.

mine, but comes into notice gradually toward the west as the zone of lesser movement is approached. In the National mine it occurs in the proportion of about half and half, while in the north division the amount is much greater. A piece of rock, of a given size and degree of dissemination from the Snowstorm mine, will carry double or more the value that rock of the same size and degree of dissemination in the north division would, and at least one and one-half times that in the National mine, although some portions of the latter are almost as good.

The Snowstorm mine I consider an example of the enriching effect of the fault dams. The best ore lies against the side fault, and on the dip the necessary distance up the strata to escape moisture effects from the lower dam westward from the dams, the ore gradually becomes lower in grade. In all probability this will be the rule in the National mine. If the main adit were extended ahead, the beds would be found at no great distance, and the point of strike change determined. However, the smashing effect may be great enough to allow water circulation to the detriment of the ore. Favorable country should be found on the other side of the strike change.

Everything points to the presumption that the rocks along the strike west from the Snowstorm mine are favorable prospecting territory if exploration be conducted low enough to get into the influence of the syncline fault. The beds are well impregnated west of the No. 3 level, and in adjoining ground show marked improvement in the lower levels over the upper. Properties working nearest the syncline fault dam have a distinct advantage over those higher up.

Range of Termination

It has previously been said that the copper beds will end on the dip into the fault occupying the centre of the syncline. For the south division, this will give them a range of from about 4700 ft. above sea-level, at some distance below No. 3 level of the Snowstorm mine, to about 3250 ft. above sea-level at the National mine end. The latter level is about that of the town of Mullan. The distance on the dip will give much greater stoping length. The copper beds in the north division will not go so deep, because of flatter dip and the closer proximity of the syncline fault. The point at which they will intersect will be between the National lower adit-level, or 3963 ft. above sea-level, and the 3250-ft. point mentioned. According to the interpretation here offered, the prospects lying between the Snowstorm and National mines are working too high in the strata to be good mining risks. The No. 4 adit of the Snowstorm company at its 3990-ft. elevation above sea-level would cut into the heart of the copper beds at about the right distance above the syncline fault and serve as the prospect adit of all under one management and plant. The work in the Missoula Copper group should be at least 500 ft. lower vertically. The beds show a marked increase in copper content on the present working level over the upper (they average around 0.6%), and driving along the strike will only serve to emphasize this fact instead of developing shipping ore. Chances are highly favorable for 1½% ore as the syncline is approached. The long adit of the Copper King group cuts across the Wallace and St. Regis copper beds, and the owners dissipated their energy and resources in following scattered bunches in fractured areas adjacent. Extending the work northeast, directly across the beds, would bring it, in from 1600 to 1800 ft., to the copper beds in the Revett, and at a zone 570 ft. below the Missoula group workings. This is very favorable territory for pay-ore. The Copper King adit on the Mullan side of the divide is the logical point to tap and drain the country along the strike on the Canyon creek side, as it is 400 ft. lower and would save the duplication of expenditure in development. All the prospect work could be concentrated on the Revett copper beds at a favorable distance above the syncline fault to work in ore the whole distance. Water enough issues now from this adit from certain strata to mill 1000 tons per day in a plant of the Callow type. The mill should be placed below the mine. The chances are good for a large tonnage from the Canyon Creek side.

Philippine Dredges

By FRANK B. INGERSOLL

Gold dredging in the Philippine Islands has grown in the past six years from nothing to about three-quarters of a million dollars in 1913. For the year 1914 conservative estimates place the production at one-half million dollars and thereafter the increase should be rapid.

Up to the present time dredging for gold in the Islands has been restricted to one locality—the Paracale district on the Pacific coast of Luzon. There for centuries the natives have washed gold from the streams and gophered it from the veins in the hills. Toward the close of the Spanish regime an English syndicate commenced quartz mining in the district and built two small mills. Their operations were discontinued by the Philippine insurrection of 1896 against Spanish sovereignty, following which came successively the Spanish-American war and the insurrection against the United States government.

American prospectors followed the troops but no rights in mineral deposits in the public lands could be acquired until after the passage of the Act of Congress of July 1, 1902, which put into effect a mining law. Unsettled conditions which continued for several years thereafter prevented the development of the mining industry.

Six or seven years ago two American prospectors, who had been holding quartz claims, realized the possibilities in dredging the streams of the Paracale district and opened negotiations with New Zealand dredging men. As the result of an examination an antiquated dredge was procured from New Zealand. After starting at Paracale the dredge had a poor record for continuous running time and handled but very little gravel, but it astonished the mining world by saving an average of more than one dollar per yard. It has since been said that it could not have saved over 60% of the gold contained in the ground. Around this old plant, which was the pioneer, there has gradually accumulated a fleet of dredges at Paracale, now numbering seven in actual operation, with one more promised during the calender year, and others to follow.

MALAGUIT DREDGE, A YUBA BOAT, PHILIPPINE ISLANDS.

One American dredge, of modern type but small capacity, as compared with the monster dredges of California, produced about $200,000 during 1913 and paid a 50% dividend for its company. Another American (Bucyrus) dredge of the most up-to-date equipment has just been set to work. Both of these plants (each costing about $150,000) have been built with Philippine capital furnished by resident Americans and Filipinos.

The Paracale field is estimated to contain about 3000 acres of profitable dredging land which will keep a good sized fleet of dredges at work for several years. Prospecting parties have spread throughout the Islands and already several thousand acres have been proved by testing to warrant the installation of dredging plants thereon. Some of the largest operators in the world are invading the field and the future of gold dredging in the Philippines is promising.—*The Philippine Bulletin.*

Origin of the Iron Ores at Kiruna, Sweden

By REGINALD A. DALY

*Field data collected in the summer of 1914 suggests that the Kiruna ores, forming probably the largest high-grade iron orebodies now being worked in any country, are differentiates *in situ* from a magma, most of which has solidified as the adjacent quartz porphyry. That keratophyric porphyry, like the older syenite porphyry of the district, is believed to be of intrusive origin. The two porphyries together appear to represent a fine example of a composite (double) laccolith, injected into a thick, chiefly volcanic series of bedded rocks. After the injection of the quartz porphyry, the magnetite-apatite ores separated out of its magma in small nodular units. Many of these units settled to the bottom of the quartz porphyry magma, forming the main orebodies at the contact with the somewhat older, underlying syenite porphyry. Many other units, now angular as well as round, were frozen in at higher levels; these are the ore inclusions of the visible quartz porphyry—bodies which some authors have hitherto regarded as xenoliths, thereby obscuring the genetic problem.

THE VAN RYN MINE, Transvaal, yielded $2,870.000 from 439,900 tons of ore during the year ended June 30, 1914. Working costs totaled $3.84 per ton, and the working profit was $1,150,000. Two dividends of $1.08 per share were paid. Ore reserves are estimated as 1,973,312 tons of fully developed, averaging 53 in. wide, worth $6.49 per ton. There is also 1,013,330 tons of $4 ore.

*Abstract of a paper read before the Geological Society of America, Philadelphia, December 29-31.

Permanent Survey Stations

By JOHN H. EGGERS

The system of permanent traverse or survey stations, described below, was adopted on adjoining properties, under one management. The properties covered a peak and ridge and three slopes, each giving a difference in elevation of more than 1000 ft. The veins were numerous and the considerable amount of work done by the several lessees was in consequence scattered.

As developments progressed, it became desirable to have various proposed levels started at similar elevations, so that the lessees, or later the mining company, could drive through and make connections that would be suitable for tramming or other purposes. The question of a millsite also arose, and with it the problem of selecting the one most suitable for the purpose, with regard to the deeper and permanent development of the properties. Progress was measured each month, and together with the outside work the surveying was considerable.

The early surveys on the surface had been run, using small nails driven in wooden stakes, but the latter were of little account at a later date owing to the fact that various persons in going over the ground would trample them down, or sheep in passing through the country would rub against them with a similar result. In consequence, it was often necessary to run over rather long surveys to tie in new work. When such a survey had been run, there were times when an old point which might serve as a check was not available. In other words, the surveys were lacking in permanence, and this was the cause of numerous re-surveys and much added expense which have been avoided in the adoption of the new system.

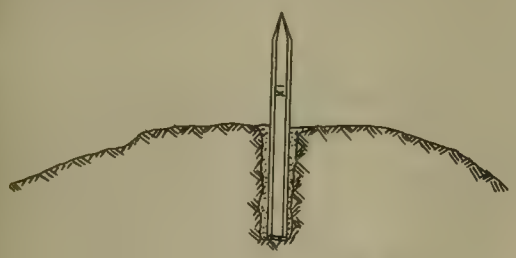


FIG. 1. STEEL POINT CEMENTED INTO CROPPING.

Instead of using the wooden stakes and nail, it was decided to use points made of drill steel, pointed at the upper end, and from 15 to 24 in. long. These points were to be cemented into holes drilled about eight inches deep, in rock in place, and some 40 odd points have been laid out in the manner described (Fig. 1).

The positions for the various points were selected with an idea to their prominence, so that they could be readily distinguished at some distance. They were also placed so that wherever possible triangles were formed, a base triangle having been previously laid out on three peaks, one of which was on the property. Throughout the main portions of the properties the points were placed close enough together so that a survey could be run from one point to another. By triangulation and the survey run from one point to another (with minor closings where convenient), it was possible to check closely the position of the permanent points, and the same applies to checking the elevations. Where the slight variations occurred in the longitude, latitude, and elevations of the points, an average was adopted in fixing its position. The points were numbered in Roman figures cut into one side of the steel.

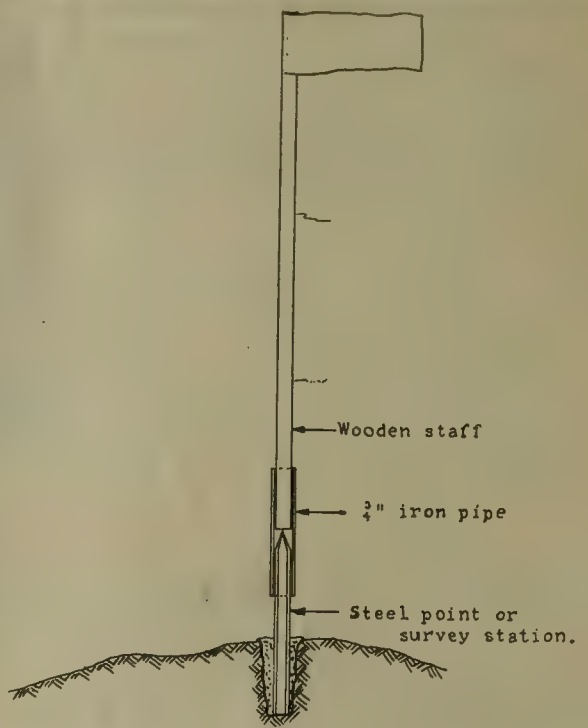

FIG. 2. STAFF AND FLAG USED ON A STEEL SURVEY POINT FOR TRIANGULATION PURPOSES.

For triangulation purposes on distant points a wooden staff is used, upon the upper end of which is nailed a white flag and the lower end of which is set six inches into a 12-in. piece of ¾-in. pipe. This pipe on the end of the staff is then set over any desired steel point (Fig. 2).

The cost of setting these points is slight and, while more expensive than using ordinary wooden stakes, this extra cost is eliminated when a second survey has to be run for want of permanent stations.

In the underground surveying, plugs and spads in the roofs are used in all work not of a very temporary

character, and it is aimed to have the heads of the plugs, and the spads, sunk beneath the line of the roof, so that they will not be shot out (Fig. 3). It has been found to be cheaper to put in the plugs than to re-run a survey underground, and this is in line with similar experience on the surface work.

FIG. 3. WOODEN PLUG AND SPAD IN THE ROOF OF A DRIFT OR STOPE, THAT IT MAY NOT BE SHOT OUT.

In the office, a card system has been adopted (Fig. 4), and all information gathered from a survey is placed therein. Total latitudes, departures, and elevations are at hand for all points, and can be readily obtained when desired. The surveys are platted on the maps from the total latitudes and departures.

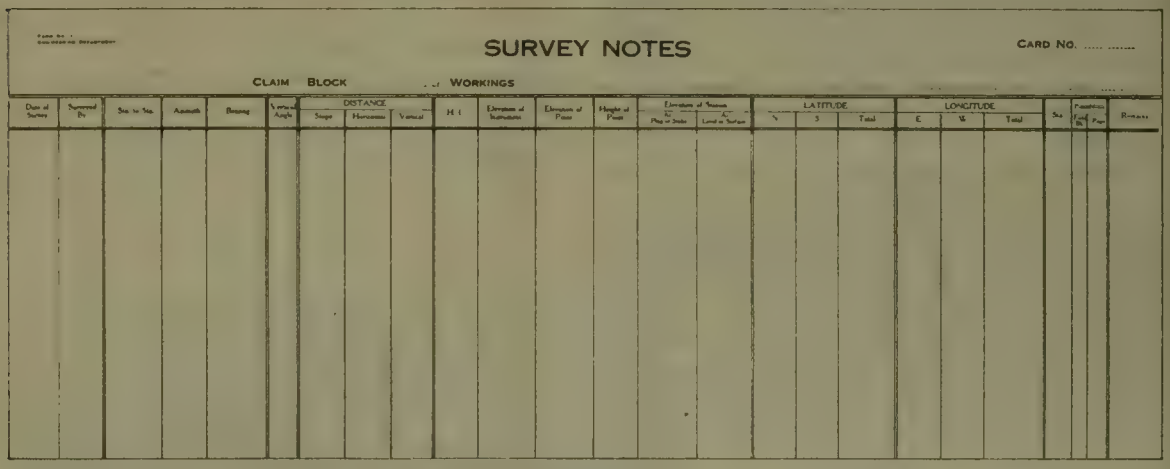

FIG. 4. CARDS FOR NOTES.

The points have proved entirely satisfactory in every way, and permit of closed surveying since they cannot be moved by the chainman or by other persons without the change being noticed. When the position and elevation of the several points have once been fixed, it is a simple matter for the engineer to pick up the known courses of any points to be used (from the map or notes), and to carry on his survey in tying in new work. He has the assurance also that his work is correct, if he has taken ordinary care, and is saved the trouble and expense of running a possible long survey. If such a system were adopted at a time when the first surveys of importance or of a permanent nature were run, a great deal of trouble, delay, time, and expense, would be saved. The system can be extended, whenever desired, by simply placing new points.

As regards the keeping of survey notes and calculations, it is advisable to have at least two sets of the same to be kept in the several offices or elsewhere, so that in case of fire at least one set will be available. The card system of notes is well adapted to this duplication of the records. It requires a certain amount of time, however, to copy the notes, and it would appear to be a good policy to have the form printed on medium or heavy vellum tracing paper, cut to the card size. The 'vellum' cards would not be injured by water, and should take the printer's ink satisfactorily. After a set of cards had been filled with the record of notes and calculations, it would be a simple matter to run off a couple of blueprints of each, and sets of the same could then be filed in the several offices for safe keeping. This should greatly reduce the time and cost of duplicating the records and avoid possible errors in transcribing.

New Cornelia Tonnage

The following estimates of total tonnage and of tonnage available for steam-shovel mining in the properties of the New Cornelia Copper Co. have been made public. The exploratory work here was described in the *Press*, January 31, 1914.*

	Tons.	Copper, per cent.
Ore estimate:		
Carbonate	11,954,400	1.54
Sulphide	28,303,600	1.50
Total carbonate and sulphide	40,258,000	1.51
Available by steam-shovel:		
Carbonate	11,954,400	1.54
Sulphide	20,526,800	1.54
Total carbonate and sulphide	32,481,200	...
Not available by steam-shovel:		
Sulphide	7,776,800	1.40
Rock stripping in carbonate and in sulphide zones:		
Rock in carbonate zone	708,400	0.65
Rock in sulphide zone	2,600,000	0.63
Total rock	3,308,400	...

COINAGE executed by the mints of the United States last year amounted to 4,194,112 gold pieces, worth $53,457,817; silver coins valued at $6,083,823; 80,568,452 copper 1-cent pieces; and coins for the Philippines, San Salvador, Costa Rica, and Ecuador.

*'Diamond-Drilling at Ajo, Pima County, Arizona.'

Self-Dumping Bucket

Where shallow shafts are grouped around a central mill, storage dump, or treatment plant, considerable economy may be effected by use of overhead wire rope arranged for combined hoisting, transporting, and dumping material. The accompanying figures show one such system as applied in the placer mining regions of central Alaska. Here one man hoists the gravel, transports it to stockpile or sluice, and dumps it, without changing his place. The principle is the same as in the familiar hay-carrier and loader on the farms. The

SELF-DUMPING BUCKET AND CARRIER USED AT FAIRBANKS.

bucket travels on a fixed wire to the top of the shaft, and then, the carrier engaging a lug, drops down the shaft. The man at the bottom detaches one bucket, attaches another, signals the engineer, and the rest of the work is automatic. A similar device has been used to some extent at Joplin, Missouri, to bring zinc ore from several shafts to a common terminal.

Moisture in Blasting Powder

As blasting powder is made up mostly of nitrate of soda with 10 to 15% of sulphur and charcoal with no liquid ingredients, it is considered solid. For this reason it is not affected by cold and, hence, will not freeze. On the other hand, hot weather does not affect it, because it requires a much higher temperature than any man could stand to ignite it. Ordinary handling and shaking in transportation does not affect it, according to F. H. Gunsolus, of the Du Pont Powder company. Nitrate of soda attracts the moisture in the air; consequently when exposed to the air in the mines or storage places, it rapidly takes up the moisture and soon loses its explosive force or strength.

The Regional Alteration of Oil Shales

By DAVID WHITE

"The examination of 'oil rocks,' such as cannels and richly bituminous shales which yield petroleums on distillation, lying in or beneath coal-bearing formations, shows that the organic matter of the shales, etc., is, in general, regionally altered and carbonized together with the coals, the alteration of the organic débris by the dynamic agencies being parallel in both. A study of the distribution of petroleums and their salient features seems to show that: (1) No commercial pools of oil are to be found in regions where the coals in or above the oil-bearing formations have reached the stage of carbonization at which the fixed carbon (proximate analysis) exceeds 70% of the pure coal, though gas pools diminishing in importance may lie beyond; (2) in regions of complete anthracitization the carbonaceous matter in the associated shales is correspondingly fixed; (3) the oils of pools in regions of relatively high fixed carbon in the rocks are, in general, highest in saturated hydrocarbons, and so highest in hydrogen and lowest in gravity; (4) in passing into zones of successively lesser alteration of the organic débris, the oils are less refined and the unsaturated and heavier hydrocarbons are, on the whole, more and more in evidence, the lowest grades of oil being found in formations in which the solid fuels are lignitic in rank; (5) while the residues of the organic débris are progressively altered, with the elimination of oxygen, nitrogen, and hydrogen, with some carbon, to composites progressively richer in carbon, the liquid distillates in the rocks as the alteration advances, become richer in hydrogen; that is, while the carbonaceous residues in the rocks become more distinctly carbonized, their liquid hydrocarbon distillates become more fully hydrogenized, the processes being, in a way, complementary.

Occurrences of abnormally high-grade oil in low-grade regions are probably due either to filtration or to migration from more altered rocks below. In cases of igneous rock metamorphism the effects may be erratic, distillates in small quantities being occluded in the magma, which also may contain inclusions of the mother rock. The limitation of commercial oil pools to regions of not too advanced alteration of the buried carbonaceous deposit bears unfavorably on the 'inorganic' theory of the origin of petroleum.

PROFITS of the Aramayo Francke company, producing tin and other metals in Bolivia, was $672,000 in its last financial year, against $720,000 in the previous term. The price of tin affected profits. Four dividends of 12c. each and a bonus of 36c. per share were distributed.

*Abstract of a paper read before the Geological Society of America, Philadelphia, December 29-31.

DISCUSSION

Readers of the MINING AND SCIENTIFIC PRESS *are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.*

Smelting in Georgia

The Editor:

Sir—I have read with interest the article entitled 'Gold Mining in Georgia,' which appeared in the *Press* December 19, and which conveys interesting facts as to ore treatment in that somewhat neglected mining region. Perhaps a few words of comment may not be out of place. I was surprised to hear that ores so complex as those described by Mr. Hafer had been found in the Appalachian country, and I must say that the miners went about their treatment in a manner that evinced correct judgment. The Seminole mine, judging from the too brief description, seems to be a fairly extensive property, from which a good output doubtless will some time be obtained; although it would appear of rather low grade according to our present standards. Orebodies reaching 15 ft. in width, of a variety amenable to ordinary methods of treatment, are certainly not to be despised. In addition to the stated resources in low-grade concentrating material derived from the vein, Mr. Hafer speaks of richer material suitable for shipping to outside (no doubt northern) smelters, and also of wall rock "heavily impregnated with auriferous sulphides." All this is quite flattering, pointing ultimately to extensive mining, concentrating, and smelting operations. The general plan of work seems to have harmonized perfectly with the conditions, embracing wet concentration in steps, followed by blast-furnace smelting of the dressed material, and the shipping of the resulting copper matte, with the incidental recovery of the lead (or part of it, more likely) in the form of base bullion. This seems impeccable practice, and although one may easily criticize some of the details of the process, the whole scheme strikes me as commendable; it is only in details that it is weak. As for these, it is of little use to call attention to defects in planning, without pointing out remedies. Nevertheless it is always interesting to trace the steps by which such installations are built, and to endeavor to elucidate the mental processes of the designers. The problem was not a simple one. The ore is rendered more difficult of treatment by reason of the inclusion of four metals—gold, silver, copper, and lead, the last of which especially complicates the metallurgical process. Evidently this fact was not fully appreciated, since no provision was made in the concentration apparatus for the separation of the galena from the other sulphides, a not difficult matter when the classification is carried to a sufficient extent. The best that can be done in such a case is to use tables which, like the Wilfley, admit of taking off a produce of pure or nearly pure galena, which might in the Seminole works be abundant enough to justify such a course. It may be, however, that the designers thought it wiser to sacrifice the lead, the inevitable result of the style of smelting which was evidently adopted. To carry out the plan suggested would require a much more elaborate ore-dressing plant than that spoken of by Mr. Hafer, for the inability of one jig reinforced by a couple of Bartlett tables to deal efficiently with so complex an ore is self-evident. Again, the free gold which exists in the surface ore—a fact known from earlier times—was seemingly neglected. The proposal now is to add stamps and tables to the already existing plant, in order to save the free gold. But may I suggest that this result could probably be better achieved by fine crushing all the tailing in a tube-mill, and passing the pulp over copper-plates or through a Pierce amalgamator or some equivalent device? The removal of all, or even a tolerable part of the sulphides (which are chiefly iron pyrite) can only be done by adding some regrinding apparatus for the jig and table middlings, and when this is effectually accomplished it should not be difficult to secure the free gold. I take it that the major part of that metal is included within the sulphides. Whatever means may be employed to separate the sulphides from the ore or from each other, the next logical step is smelting, either in blast or reverberatory furnaces, the former preferably on account of the lead content. Although the quantities dealt with were so minute according to our modern notions, there was and is opportunity for the application of much metallurgical knowledge and experience.

I admire the courage, though not the good judgment, of a metallurgist who at this day, or even a decade since, will set about to build and run a furnace such as described by Mr. Hafer. American practice in furnace building obtains now over the whole civilized world, and it prevailed almost universally when the little Augusta stack was set up. Unless it might be some devotee of the old German school, I cannot imagine who would have built such a thing as "a square brick furnace 2 by 3 ft., with three tuyeres all on one side." Can it have been a case of atavism, or possibly a recrudescence which will set us to awaiting expectantly for larger construction of the same kind? I would take more pleasure in building than in running such a furnace; for I have reason to know that to keep such an affair in proper trim is a most nerve destroying proceeding. It would have been far better, it seems to me, to have put up a small round

water-jacket of an approved pattern, arranged to avoid, or at least to minimize, the obstacles to proper running, the more so as a round cupola is more convenient to work, and more easily set right when in difficulties than any square or prismatic stack. By providing a removable hearth, as should always be done in small scale work, and by spacing the tuyeres evenly about the periphery, with provision for their convenient 'pricking,' which is a necessity, the ordinary evils of smelting on a miniature scale are so far done away with that even the almost inevitable freeze-ups are matters of little moment. By letting down and removing the crucible the whole furnace may be emptied, the crucible replaced, and the blast turned on again in two or three hours. Up to a capacity of 100 tons, or even more, a round furnace answers better than a square one, especially as a simple bell and hopper arrangement may be used for feeding, doing away with the laborious operation of shoveling in and spreading the charge by hand. The colossal iron furnaces of today are invariably circular in section, and are fed in this way. The use of the bell and hopper device confers much benefit, especially in the absence of skilled labor.

The final product of the Seminole works was copper-silver-gold matte, containing from 15 to 20% copper, 20 oz. silver, and from 2 to 3 oz. gold per ton. The grievous mistake of shipping this comparatively low-grade material, containing in gross only from $80 to $110 per ton, instead of concentrating it by repeated fusions with quartzose ores to at least 60% copper and proportional gold and silver, is almost reason enough for condemning the whole project. Nothing is easier to conduct in a cupola, and this should be done, in order to diminish so far as possible, the freight and treatment charges of which Mr. Hafer complains. These must have amounted to from $13 to $16 per ton of matte, or in the neighborhood of one-sixth of its total value. Thus, the net return of one ton of concentrate could not have been more than $13 to $18, from which must still be deducted the cost of mining and concentrating the much larger amount of crude ore, as well as of smelting the dressed stuff. Hence the importance of enlarging the scale of operations, and of making a richer product. I cannot attach so much importance to the cost of fuel and other necessities of smelting as Mr. Hafer does, nor can I see that a wagon haul of 12 miles on both incoming coke and outgoing matte would make much difference. The Tennessee Copper Co., situated similarly in a geographical sense, obtains its coke, I believe, for $4.50 per ton, while common labor costs but a little more than $1 per day. Oak wood, I understand, is bought by them for $1.50 per cord. In what part of the world, I would ask, can these conditions be bettered?

The Georgia company, I observe, practised briquetting of its ore, using lime and cement as binders. Lime is commonly used in many works; but the use of cement, although suggested many years since, so far as I am aware, has never come into regular or extensive use for this purpose. It is comparatively an expensive material, and unthinking persons would naturally jump at the conclusion that it would cost too much to briquette smelting materials by its aid. But its holding power is so great that there will still be economy in exceptional cases by employing it instead of lime or even clay, which are the usual binders. I should be glad to hear of some quantitative experiments or practice in this direction. Cement, of course, while basic in composition, is not, like lime, wholly so, and therefore is less useful as flux for silicious materials. Everybody knows the value of lime for that purpose, and the metallurgist would be safe in assuming that an addition of this base would improve the running of furnaces handling such material as the Seminole concentrate. The minute quantity of cement required would scarcely affect the running of the furnace one way or another, and even the lime necessary to bind the fine material would almost be unnoticeable. The slag, no doubt, was somewhat aluminous, and it may have been deemed unwise to mix the concentrate with clay, the usual binder. About 10% of this answers the purpose, or rather less if the pugging be thorough. Clay is, on the whole, a better binder than lime, since the grout holds together better under the influence of heat. I do not know by experience how the cemented briquettes behave in the furnace, but it is natural to suppose that they would lose water and fall to pieces, as when lime is used.

I judge that the Seminole mine is a fairly promising property, which has suffered somewhat from unpractical methods, but which in the hands of professional operators might be made to show a good profit. It evidently came very near success in this attempt, and in the light of the experience thus gained will doubtless do better next time. No doubt the right man will get hold some time and make it a success. Meantime the owners should not feel chagrined that their efforts have not met with entire success, because one can point to many larger and more noted concerns which have suffered quite as much from doing the right thing in the wrong way.

HERBERT LANG.

Oakland, California, December 19, 1914.

Tin Mining in the Federated Malay States

The Editor:

Sir—With regard to my article in your issue of September 26, may I be allowed to explain that it was written in February, when the price of tin was in the neighborhood of £180 per ton and the world's trade was still in full swing? However, the forecast of what would result if the price fell to £140 per ton has been amply justified. A number of mines have been shut down, while many others are now operating at a loss. Many Chinese mines which cannot be paying their way are still kept going, because the mine coolies are only being fed and given small cash advances, but will not get a full settlement until Chinese New Year on February 14,

such being the custom; therefore the owners prefer to continue in the hope that conditions will improve and enable them to pay their labor. Should the price of the metal remain depressed until Chinese New Year, most of these mines are certain to stop work, which will have a serious effect on the F. M. S. output.

I made a mistake in crediting the Chinese mines with 85% of the total output for 1913. No official figures had been published at the time, and the computation was made from the returns of the non-Chinese mines quoted in the local press. The correct proportions are: 74% or 37,000 tons from the Chinese, and 26% or 13,000 tons from the European and Australian mines.

E. J. VALLENTINE.

Intan, Upper Perak, November 16, 1914.

The Whim Well Copper Mine

The Editor:

Sir—I note in your issue of October 31, 1914, a paragraph in regard to the Whim Well Copper Mines, Ltd. There are several misstatements of fact in that paragraph, and I am sure you will be glad of an opportunity of correcting these.

It is stated that owing to Germany being practically the only buyer of copper ore, the Whim Well mine has been forced to close down. The Whim Well mine has never sent any ore to Germany, and I may say that practically the whole of the ore from that mine was sent to and purchased by smelting firms in England. In view of late discussions as to German trade in ores, this fact will probably be of considerable general interest. The statement that the mine employed over 300 men is incorrect. The employment has rarely exceeded 150 men and has for considerable periods employed less. The figure given as the annual exported tonnage of ore (10,000) is substantially correct.

The statement that the Company has been operating a Murex magnetic plant is hardly accurate. Owing to a number of minor defects in the crushing plant and to other causes, the Murex plant was never run continuously or on a commercial basis and never reached the capacity of 200 tons per day. Only a few thousand tons of ore was treated by it. The plant is today practically complete, awaiting mainly an adequate water supply, which can readily be installed. When operating, the ore to be treated by the plant, including waste to be sorted out, is expected to be nearly 200 tons per day, though something less.

The statement that the mine was in bad order is incorrect. It has been worked by open stoping, on account of selective mining being so far adopted. This necessitated the keeping of the stopes unfilled, to enable the surrounding ground to be worked when conditions changed. The reason for selective mining was the policy of shipping ore. This required a grade of ore higher than the average to be mined. It has been desired to abandon this system for some years past, but circumstances have led to its continuation until the late closing on the outbreak of the war. Meantime it is well to state that not one serious accident has ever occurred through the system used, that is, on account of the so-called 'bad order' in which the mine is stated to be. This is an exceptionally good record. It is not correct that the ground worked during the immediate and near past has been more shallow than the average previously. The inspector of mines has required certain filling or timbering to be done before stoping in certain parts is restarted, owing to the height of the stope roof in certain places. Certainly it is highly desirable that selective mining will not be resumed and that suitable system of filling accompanied by the extraction of the ore on an average grade basis, be started. I have no doubt that this policy will be carried out.

I have never, either two years ago or at any other time, estimated the ore reserves at 1,000,000 tons of 5%. It seems a pity that those responsible for supplying such news to the press do not acquaint themselves with the facts before making such statements. Neither did I estimate that, with copper at £70 per ton, a profit of £60,000 per year would be made. This fact obviates any necessity of denying the final statement that later events reduced this estimate considerably.

I consider that there is promise, or reasonable expectation, of fully 1,000,000 tons of 5% *oxidized ore alone* existing in the mine, and that this ore can be worked at a considerable margin of profit. This is a very different matter. I might deal with this more fully, but such does not seem to be called for in this letter, which is written to contradict erroneous statements.

H. R. SLEEMAN.

London, December 10.

[In this instance our correspondent was evidently misinformed. Mr. Sleeman, as manager, evidently has the correct information on the various points. In our issue of May 23, 1914, will be found an abstract of the annual report issued by the Company in which the developed ore was given at about 100,000 tons of 5%, while the 'probable' ore above water-level was stated to be 1,000,000 tons, the figures agreeing with Mr. Sleeman's present estimate. The difference evidently rests upon confusion of the estimate of 'probable' and developed ore. Evidently, too, the Murex plant was stopped after the annual report was written. We accept Mr. Sleeman's statement on this and other points without reserve, and thank him for calling attention to the error.—EDITOR.]

THE RANDFONTEIN CENTRAL COMPANY, Transvaal, shows the following results for the nine months ended September 30, 1914: Development, 78,933 ft.; ore reserves, 8,664,262 tons; ore mined, 1,968,110 tons; sorted, 6.04%; ore milled, 1,849,228 tons; gold yield, $10,100,000; yield per ton, $5.58; cost per ton, $4.02; and profit, $2,880,000.

USE of the phrases 'German silver' and 'German steel' has been stopped in England since the war, and 'nickel silver' and 'nickel steel' are the descriptive terms used.

CONCENTRATES

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, or smelting.

ELECTRIC POWER at the St. John del Rey mine, Brazil, generated by water power, costs 3.24c. per horse-power per 24 hours.

MOLYBDENUM ORES at the Knaben mine, Norway, are now being treated by the Elmore process in place of water concentration. The product contains 80% MoS_2.

TAXES paid by the St. John del Rey Mining Co. to the state and federal governments of Brazil, during the half-year ended August 31, 1914, amounted to $62,400, including some transport charges.

WHERE TREES ARE SCARCE in parts of the West, sage-brush is used for fuel, according to the Forestry Service. In Nevada the large main stems are trimmed by Indians at $3 per cord and delivered to the user at about $6.50. Sage-brush burns rapidly and is rather dirty, but produces good heat.

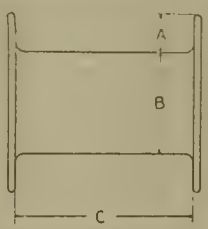
COLD WEATHER at Wardner and Kellogg, Coeur d'Alene district, Idaho, has frozen the water in supply pipes. These were covered by 12 in. of earth, but the frost has penetrated 20 in. Thawing has been done by electricity, by which a heavy current is passed through the mains. This is also done at Spokane, Washington.

'RADIUM ELEMENT' is the correct term to use in discussing treatment by radium, contained in radium bromide, according to William H. Cameron in *Radium* for December. Only the radium element content of any salt is therapeutically active, the bromine in the radium bromide being of no therapeutic value. In this issue mentioned, the writer discusses numbers of cases treated by him and the results.

MINING COSTS at the Iron Blossom mine, Tintic, Utah, last year, were as follows: development, 8755 ft., 21.5c.; stoping 40,480 tons of ore, $3.486; tramming, 10.4c.; hoisting, 39.9c.; surface expenses, 15.2c.; surveying and assaying, 14.1c.; general expense, 17.1c.; pumps, 0.6c.; exploring, 69.1c.; and accident, 0.1c., a total of $5.366 per ton. Driving in waste for filling old stopes increased the cost.

BREAKER plants in the anthracite coal regions of Pennsylvania, which handle coal and produce certain sizes, often burn. Conflagrations are quick and hot, fed by the coal and the numerous drafts throughout the immense open structure. Sprinkler systems that can be turned on by hand from outside the buildings are being installed in 14 of the wooden anthracite breakers of the Lehigh Valley Coal Co., and installations in two more are planned.

DYES FROM SULPHUR have been used only for dyeing cotton, but two chemists at Huddersfield, England, have discovered that sulphur dyes may be used with success on wool, silk, artificial silk, hemp, and other fibres, which can be treated either separately or in combination. These dyes are cheap, and, unlike aniline dyes, add to the properties of milled cloth. Great hopes are held in England for the new methods, as there is a shortage of German dyes.



TO FIND ROPE CAPACITY OF ANY SIZE DRUM.

ROPE CAPACITY in feet of any size drum may be computed by the following rule, according to *Loschen's Hercules*: Add the depth of flange (A) to diameter of drum (B), multiply the sum by the depth of the flange (A), multiply the result by the width of the drum between the flanges (C), and multiply product by figures in column opposite rope size (the dimensions of A, B, and C to be in inches). Example:

$$(A + B) \times A \times C \times \text{multiplier}.$$

Inches.	Multipliers.	Inches.	Multipliers.
¼	4.16	1⅜	0.138
⅜	1.86	1½	0.116
7/16	1.37	1⅝	0.099
½	1.05	1¾	0.085
9/16	0.828	1⅞	0.074
⅝	0.672	2	0.066
¾	0.465	2⅛	0.058
⅞	0.342	2¼	0.052
1	0.262	2⅜	0.046
1⅛	0.207	2½	0.042
1¼	0.167		

ROPE DRIVES have many advantages, the principal of which are the following: (1) Rope drives furnish smooth, continuous action. (2) Rope drives are low in cost of installation and high in efficiency, being from 87 to 97%. (3) The ratio of revolutions can easily be changed by a new small pulley. (4) Changes of pulley alignment which are so destructive to gears or belts, do not affect ropes. (5) Freedom from shut-downs by accidents is assured. The breaking of a tooth is serious; a temporary overstraining of ropes does very little harm. (6) Rope drives are noiseless. (7) The engine or motor may be situated away from the grit and dust of the mill. (8) Freedom from shocks is obtained, as ropes are elastic.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

NEW YORK

NEW KEYSTONE.—INSPIRATION DEAL DELAYED.—ALASKA GOLD FINANCE.—AMERICAN ZINC CO.—ANACONDA.—LEAD AND COPPER EXPORTS.—THE COTTRELL DINNER.

A hitch has developed in the proposed consolidation of the New Keystone and Inspiration Consolidated Copper companies, as J. A. Butler has secured an injunction restraining the Keystone company from carrying out the consolidation, and C. H. Pforzheimer circularized the stockholders in regard to it. Because of this, the meeting of the stockholders was adjourned until January 15, when about a dozen stockholders were present, especially those who were attempting to block the sale. They presented an amendment to the resolution providing for the sale of the Company's assets, calling for the appointment of a committee of five stockholders, two of them to be C. H. Pforzheimer and F. E. Huntress, to appoint two engineers to report on the Keystone property as to tonnage and advisability of independent operation, and if possible also to report on the financial and physical condition of the Inspiration. These majority shareholders believe they should receive a better price for their shareholdings than has already been arranged for, and do not seem to appreciate the fact that the tonnage of ore in the Keystone property is so small that a large part of the operating profit on it would be eaten up in providing for repaying the cost of construction of mine plant and mill, although it will yield a substantial profit when milled in the larger plant of the Inspiration.

The Alaska Gold Mines Co. has called a special meeting of stockholders to be held at Portland, Maine, on January 21, to vote on a proposal to issue $1,500,000 of 10-year 6% bonds, convertible at any time after maturity into shares at $30 per share and redeemable at $110. Also to take action in regard to the proposal to increase the capital of the Company from $7,500,000 to $10,000,000; 50,000 of the new shares to be set aside for the conversion of the debentures and the rest to be held for the conversion of any future debentures which may be authorized. The accompanying circular says that the average grade of the ore developed has proved to be higher than $1.50 per ton first estimated, and the tonnage has also proved much larger than expected. The mill, which is about ready to start, although designed for a capacity of 6000 tons per day, will treat 8000 tons, and the recommendation is that milling operations be increased to 20,000 tons per day as rapidly as practicable.

The president of the American Zinc, Lead & Smelter Co., H. S. Kimball, has stated that in spite of the unsatisfactory conditions prevailing during a large part of the past year, the Company came through the year with a surplus of $70,000 above fixed charges. He estimates that the earnings during 1915 will be at least $700,000, and perhaps may reach $1,000,000. The flotation process at the Mascot property in Tennessee is giving excellent results, and the present rate of earnings of the Mascot is at the rate of over $400,000 per year. The Missouri property of the Company is earning about $100,000, and the acid department is also doing well, as it contributed about $90,000 to the operating profit last year.

The output of the Anaconda Copper Co. for 1914 is given as 225,645,000 lb., as compared with 271,000,000 lb. the preceding year. B. B. Thayer states that some $5,000,000 to $6,000,000 will be spent on the program of construction which the Anaconda company contemplates. Part of this will be spent for doubling the refining capacity at Great Falls, and the rest of it on changes and additions to the Anaconda plants which are in process. Frederick Laist, who developed the leaching process of the Anaconda, has been made chief metallurgical engineer for the Company, and now will have general oversight of metallurgical operations both at Great Falls and Anaconda.

Ordinarily very little lead is exported from the United States, but recently there have been good sales for export, especially to Italy, Russia, and France. One of the producers has estimated that the present exports averaged 12,000 tons per month, compared with 5000 tons in ordinary circumstances. Russia has bought some 10,000 tons during the latter part of 1914. The output continues at about two-thirds of normal, and unless there is a further advance in prices, there is no probability of an increase.

There has been no improvement in the copper export situation, although sales have been rather better than before. The steamer lines to Sweden have followed the example set by the Italian lines earlier in the year, by refusing to accept shipments, since so many vessels have been detained, and the companies are not willing to have their vessels held up at a considerable expense to themselves. Arrangements have been made for the certification by the Swedish minister at Washington that shipments of copper to Sweden were intended for manufacture in Sweden and not for re-shipment to Germany, but the shipping companies do not consider this a sufficient guarantee that their vessels will not be detained. The Italian companies will now accept copper for Italy where same is accompanied by similar documents, but they ask freight rates of about double the ordinary charges. What the producers most complain of is the long delay in acting on shipments. Over 30 shipments are still detained out of a total of 45, and no settlement has been made, although some of these detentions date back as far as August 15. Negotiations between the United States government and that of Great Britain are still in progress, but meanwhile it is difficult for either the copper sellers or the shipping agencies to know just where they stand.

On Friday evening, January 16, over one hundred members of the American Institute of Mining Engineers, American Electrochemical Society, and the Mining and Metallurgical Society of America gathered at the Hotel Plaza, New York, at a complimentary dinner tendered to F. G. Cottrell in appreciation of his services to the metallurgical profession. The dinner was presided over by Sidney Jennings and the first speaker of the evening was Charles D. Walcott, director of the Smithsonian Institution, who told how the Research Corporation came to be organized to administer the valuable patents which Mr. Cottrell had so generously given to the Institution for the benefit of research and the general public. W. L. Saunders next spoke for the Institute, relating some of his experiences with inventors whose patents were valued at a million dollars, saying that this was the first instance he had met where that valuation of patents had been placed upon them by the corporation which owned them rather than the inventor, and paid tribute to Mr. Cottrell's unparalleled generosity in dedicating his patents to public service instead of personal profit. F. A. Lydbury next spoke for the American Electrochemical Society, and told some reminiscences of the time when with Mr. Cottrell he was working as a

student in Ostwald's laboratory at Leipzig. W. R. Ingalls, speaking for the Mining and Metallurgical Society, made an excellent speech, and Mr. Cottrell followed with a response in which, with characteristic modesty, he ascribed the success attained in developing his patent, and in administering the affairs of the Research Corporation, to everyone except himself. It was a source of general regret to all present that Mrs. Cottrell was unable to attend the dinner. The committee sent to her in California a night letter voicing the general regret that she was not present to share in receiving the expression of appreciation.

At the annual meeting of the Research Corporation, held on January 5, 1915, the following minute was adopted: "In 1911, Frederick G. Cottrell, B.S., Ph.D., offered to transfer to the Smithsonian Institution substantially all his rights to his inventions and patents covering the processes known as the electrical precipitation of suspended particles, in order that the profits resulting from the application of the patents, already well assured, might be applied to the advancement of scientific research and investigation." Naturally this proposition was at once regarded as both generous in spirit and highly original in conception. It was Dr. Cottrell's ideal to render the discovery already made the mother of new discovery, and thus contribute to the scientific and technical development of the industrial arts. This far-sighted and patriotic conception found its realization through the Research Corporation, which for administrative reasons was substituted for the Smithsonian Institution as the custodian of Dr. Cottrell's endowment. The objects of the Research Corporation as stated in its charter are as follows in part: "To provide means for the advancement and extension of technical and scientific investigation, research, and experimentation, by contributing the net earnings of the corporation, over and above such sum or sums as may be reserved or retained and held as endowment fund or working capital, to the Smithsonian Institution and such other scientific and educational institutions and societies as the board of directors may from time to time select in order to enable such institutions and societies to conduct such investigations, research, and experimentation."

WASHINGTON, D. C.

MINING EXPERIMENT AND MINE SAFETY STATIONS LEGISLATION.—COPPER SHIPMENTS TO EUROPE.

Mining legislation in Congress is now centring around the bill of Martin D. Foster, Congressman from Illinois, to provide for the establishment and maintenance of mining experiment and mine safety stations, for making investigations and disseminating information in mining, quarrying, metallurgy, and other mineral industries. Meetings have been held to advance the bill in the House, in the hope of procuring its passage on one of the suspension days, but while the legislation in principle is thought generally favored, it involves the large appropriation of about $625,000 if the complete number of stations, eleven (one to be in California), is to be authorized, and as Congressman John J. Fitzgerald, of the appropriations committee, is combatting all new appropriations, and especially those looking large, it is expected that he will raise every obstruction against the bill in a parliamentary way, and it would not be at all surprising if he could block the passage of the bill toward enactment. Then, moreover, the bill would have to pass in the Senate, and the session is now getting short. It is just possible that the House will assent to the passage of the bill with only one or two stations. That would be an opening, and the rest would follow subsequently. Mr. Fitzgerald knows this. A good deal of urgency can be shown for the measure from a sanitation point of view alone in the mines. The great death rate from miner's consumption is most striking. As is shown in Missouri, in certain districts, it amounts to 10%. It is felt that this situation ought to be met and would be met by the bill mentioned. The appeal from this point of view seems unanswerable, and it may have its effect in Congress. At all events, it is the plan to present it. Moreover, the point is going to be made that Congress is more than ever ready to respond to the needs of the agricultural world, appropriating millions of dollars every year for development, and that the mining world should be permitted to share in the benefits of Congress on this score.

The copper situation, with respect to shipments to Europe, continues to be watched here, and especially by T. J. Walsh of Montana, who has given it his special attention. Watchful waiting continues, and there seems nothing else to do.

HOUGHTON, MICHIGAN

REOPENING MINES AND INCREASED TIME WORKED.—C. & H. REFINERY VISITED BY BUTTE OFFICIALS.—COPPER INTERESTED IN GOLD.

Every day or so the copper country learns of the reopening of some mine, an increase in the working force, or a return to full time. Such news is certainly good news, and it gives ground for a spirit of optimism for the year 1915. A report comes from the Iron River district that the Munro Iron Mining Co. will resume operations about February 1, orders having been received from the East to that effect. The Rogers and Chicagoan mines will open on full shifts, and the sinking of the Hiawatha shaft will be continued.

The announcement of the Copper Range Consolidated company that the Baltic, Champion, and Trimountain mines would return to full time schedule was well received here, and especially by the people of the south range towns. Since August 15 of last year the Copper Range mines have been working half a month and shutting down for the other half. The new schedule means full time until next spring at least.

Officials of the Butte & Boston Smelting Co., of Great Falls, recently visited the Calumet & Hecla electrolytic refinery at Hubbell. It is reported that a $2,000,000 plant is to be built by the Butte & Boston company. The visiting party, consisting of the general superintendent, master mechanic, gen-

WATER DRILL IN A MICHIGAN COPPER MINE.

eral foreman of electrolytics, and a draftsman, are on a tour of inspection of electrolytic plants in the East.

For the past five or six years several people at Houghton have been interested in the development of the Oro Belle gold property at Hart, San Bernardino county, California. About a year ago the office of the Company was moved to Houghton, since practically all the stock was held by residents of the Lake Superior region. Great things were expected from the Oro Belle, but as yet no returns have been received by the shareholders. At a meeting of the directors held at Houghton recently, a contract was closed with the Tonopah Belmont company of Philadelphia. After an examination by its own engineers, the Tonopah company accepted the contract to continue the development and equipment of the Oro Belle property.

JOPLIN, MISSOURI

Open-Pit Mining in the Webb City-Carterville District.—Gem, Century, Hurry-Up, and Other Companies' Operations.—A Good Investment.

Open-pit mining is in progress on the Center Creek Mining Co.'s land between Webb City and Carterville, Missouri, the average recovery of zinc-blende and galena being better than 2%. On this land the first mining in Webb City was started over 50 years ago, and operations have been almost continuous since that time. The first mining consisted of lead ore development, 'pay dirt' being opened at places within five feet of the surface. Gradually the operations developed to a more elaborate plan, deeper development being done until the land was opened to a depth of 200 ft. In this ground an extensive formation of hard sheet-ore is encountered, but the upper deposits are all of a soft formation or disseminated in brecciated chert. Remarkably rich soft-ground deposits have been worked at various times, but in recent years much of the property has become so intricately cut and re-cut that good ore formations could not be reached because of the possibility of caving ground. Three separate companies are now engaged in 'pulling' the old ground, by going under the old workings and permitting the ore from above to slide down, the result being that several large caves, that reach upward to the surface, have appeared. The companies at present engaged in this form of development are the Incline Mining Co., the Wisby Mining Co., which is working the old Comet Mining Co.'s lease, and George Moore and associates. The most important sheet-ground development is that of the Ramage mine on the Center Creek land, the blende recovery in recent months having been in excess of 4 per cent.

The Gem Mining Co., situated in an isolated region in the James River country, eight miles southeast of Springfield, Missouri, has resumed operations after an idleness of five months. During the time the mine has been non-productive considerable development has been done, the result being that a good body of choice zinc ore has been opened in a new shaft at a depth of 150 ft., and this will be hauled by aerial tramway to the mill, which is 800 ft. distant. F. R. Cook, sole operator of the property, took over the interests of J. J. Parker, who formerly was interested in the mine. The latter is an Olanthe, Kansas, physician.

The Century Mining Co., at Neck City, Missouri, made its record run recently when in a single day 70,000 lb. of zinc-blende concentrate was put in the bin. This heavy production was made by the day and night shifts. The Company has been operating only a year, having developed an untouched body of rich ore in the midst of a district that had been so thoroughly mined and prospected that almost everyone was inclined to believe that this portion of the district had seen its best days as a mineral producer. However, the Century has opened a really remarkable body of ore at a depth of 200 ft., and in addition to its exceptional richness, which yields over 12% blende, the cleaned concentrate is high in metallic zinc, always yielding above 62%, and, because of this fact, commanding a settlement of several dollars per ton in excess of the basis offerings of the smelters.

To purchase a mine for $3500, and produce enough ore during the first week's operation to pay for it, was the kind fortune that befell Thomas F. Coyne, recently, when he procured a small mine on the Missouri Zinc Fields Co.'s property at Webb City. His first week's work yielded him 100,000 lb. of lead and 90,000 lb. of zinc ore. The property has been named the Red Top Mining Co. and continues to make heavy turn-ins from a depth of 75 ft., while drilling in front of the drifts shows a good body of ore yet to be worked. The ore is hauled some distance to a custom mill for treatment.

The Hurry-Up Mining Co., operated by J. M. Smith, brought $40,000 recently when sold to Kentucky people represented in this district by J. J. McLellan & Co. The mine is on a lease of the Guinn land, and is in the heart of the North Webb City sheet-ground district. It has been a steady producer. The ore occurs at a depth of 200 feet.

John R. Grigg, Elmer Tabor, and Frank Weeks have organized a leasing company and taken over the 746-acre tract of the Saginaw Investment Co. at Saginaw, six miles south of Joplin. The land is known to contain good ore, but the biggest handicap to development has been the heavy water proposition. Even shallow work could not be carried on due to water being encountered within a few feet of the surface. The Company has installed large centrifugal pumps, and the drainage of the land has been started. Leases will be given to prospectors, and a large custom mill is to be constructed to handle the ores mined from the tract.

Carmean & Squires, operators of some of the largest sheet-ground mines in the North Webb City field, have taken over the Mercantile Metal Mining Co.'s properties, also in the North Webb City field. With the stronger ore prices that are now prevailing, a heavy production from all these large mines is looked for.

In drilling into a drift to give better ventilation, good ore was found unexpectedly by Sigler & Co. on the Rex Mining & Smelting Co.'s land, east of Joplin. The Company was working at a depth of 100 ft., the top of the drift being at 90 ft. The drill-hole went into good ore in the roof of the drift, and passing through the drift was permitted to continue downward, with the result that a stope of 18 ft. of good zinc-blende was shown.

DEADWOOD, SOUTH DAKOTA

Oro Hondo, Hidden Treasure, and Echo Mines.—Gypsum Products Manufacture.—County Roads.

Some very hard rock has been encountered in the Oro Hondo shaft, and progress in sinking the three-compartment bore has slackened perceptibly. Where formerly 60 to 70 buckets of rock was hoisted per shift, the output is now 25 to 30 buckets. The city of Deadwood has established a municipal transportation service between Deadwood and the mine, using an automobile to haul passengers and freight. Passengers are charged 10c. per trip, which is considered reasonable for the 4-mile haul. Any deficit in the revenues is met by the city council. The county has recently expended about $3500 in road improvement between Pluma and the mine.

During the season just closing, Lawrence county has spent $75,000 in road improvement, practically all of which has been done in the mining area around Lead, Terry, and Deadwood. All of the work has been under the supervision of a competent engineer, and is of a permanent character. For instance, all bridges are of steel, with concrete abutments, and the maximum grades have been kept below 8% wherever practicable. At the present rate of progress, a couple of more years should give Lawrence county the best roads of any similar mining district in the United States.

With the resumption of shaft work by the Hidden Treasure company, attention is again directed to a most interesting district of the Black Hills and it is hoped that the Company's territory will be thoroughly prospected. The formation is largely porphyritic, consisting of rhyolite and phonolite some veins have been found carrying large percentages of fluorite with encouraging silver and gold content. The shaft was sunk following one of these veins, to a depth of 200 ft., and when lack of funds caused suspension, there was a flattering showing in the bottom. The property is about five miles from Deadwood, on Deadwood gulch. Equipment includes a gasoline driven hoist and compressor. S. R. Thompson has been engaged as superintendent.

Machinery recently purchased by the Echo Gold Mining Co. has been delivered at the property at Maitland, and if weather conditions permit, it will be erected immediately after the holidays. The purchase included a 25-hp. electric-driven Vulcan hoist, an 8 by 8-in. Bury compressor, two Western air-hammer drills, a swing cut-off circular saw for the timber man, and other incidentals to make a complete equipment for prospecting. It is the intention of the Company to sink several hundred feet to explore orebodies which have been exposed on the surface and in adits.

The manufacture of gypsum products, such as stucco, or wall plaster, terra cotta tiling, and the like, has become an important industry in and around Rapid City. According to the report of the state mine inspector, the value of the products manufactured during the year ended October 31 was $59,000. This was the output of two mills. Almost entirely surrounding the Black Hills are large bodies of good-grade gypsum, which will at some future time be immensely valuable. At present the market is limited to practically the local consumption, and with the growth of the tributary sections the demand will naturally increase. It is no unusual matter to find a bed of gypsum 20 ft. thick which can be mined by stripping and open-cutting, and with cheap electric power and fuel the cost is not great; it is the freight rates that govern the scope of the competitive territory.

TORONTO, ONTARIO

NICKEL PRODUCTION OF CANADA, AND THE UNITED STATES, ENGLISH, AND GERMAN INTERESTS.—PATRIOTISM OR BUSINESS CONSIDERATIONS IN THE NICKEL CONTROVERSY.

The agitation for a complete embargo on the exportation of nickel in any form to any country outside the British Empire has not been allayed by the explicit assurance of A. Monel, president of the International Nickel Co., that every precaution is being taken to prevent the refined metal reaching Germany, and that the Canadian government is kept fully informed as to all shipments made by the Company. In view of the continued [illegible] to action by the government to stop the export of nickel matte to the American refineries a memorandum also explaining the situation was issued by the government at Ottawa on December 28. It stated that the whole subject had been carefully investigated since the commencement of the war and there had been frequent communications with the British government as to the precautions which should be taken to prevent export to Germany. The books of the Company in New York are inspected at short intervals by an experienced accountant, who goes thoroughly into all exports and reports for the Canadian government. There is also an arrangement between the Company and the British government by which certain control is exercised in London through the Company's English representatives. The steps taken by the Dominion government, it is stated, have the approval of the British authorities, who are entirely satisfied with these precautions. The widespread belief that Krupp is largely interested in the International Nickel Co. and controls its policy is thus disposed of. "The Company is not under German control, but is controlled altogether in the United States, where the majority of the stock is held. There may be a few German shareholders, but the proportion is insignificant, and there are no German directors." The document concludes by pointing out that as nickel is largely used in many American industries, the prohibition of its export, unless for very urgent reasons, would be undesirable, as it would result in great business disturbance in a friendly country. Furthermore it is stated that German interests control an output of nickel in Norway, which could furnish a sufficient supply for German requirements.

COPPER CLIFF SMELTER OF CANADIAN COPPER CO., CONTROLLED BY INTERNATIONAL NICKEL CO.

This may be taken as conclusive as regards the policy of the government in refusing to yield to the clamor of the scaremongers, and in so doing paralyze an important industry. The total export of fine nickel, contained in ore, matte, or speiss, for the fiscal year ended March 31 last was 50,580,536 lb., valued at $5,374,738, of which 43,989,648 lb., worth $4,398,920, went to the American refineries. In the course of the newspaper controversy over the proposed embargo, which has been in progress for some weeks, much light has been thrown on the real motives of the agitators. The movement is evidently being promoted by the owners of large nickel properties, who wish to shut out the International Nickel Co. and obtain large subsidies or bonuses from the government for the establishment of the nickel-refining industry in Canada. By specious appeals to the patriotism of the people, and their distrust of German influences, they have succeeded in working up a strong feeling on the subject, but the clear and explicit statement of the government has materially allayed the excitement among those who have no selfish interests to promote by it. The Alexo mine produced 878 tons of nickel ore in December.

THE MINING SUMMARY

The news of the week as told by our special correspondents and reflected by the local press.

ALASKA

Chisana

According to G. R. Goshaw, the winter has been mild, and about 250 men are living at Chisana. The trails are being improved, and considerable prospecting is being done on Ptarmigan creek. At the elections, 140 people voted, the population on November 3 being 233.

Cordova

The geology of the Hanagita-Bremner region, in the Copper River district, is described by Fred H. Moffit in *Bulletin* 576 of the U. S. Geological Survey. The examination was carried out under various difficulties natural to the area. Snow remains until the late spring. The only valuable timber is spruce, which is found in varying amounts and quality. The population is small. Trails are not well established. There is plenty of water for sluicing. Gold-bearing gravel was discovered in 1901 by prospectors from Valdez, and placer mining has been done each season since. There are a few gold lodes around Golconda creek, Bremner river, and the Copper river. Copper claims have been staked between Cañon creek and Chitina river.

Fairbanks

Up to December 31, 174,646 oz. gold had been sent out from the Fairbanks district, as the season's output, compared with 197,712 oz. in 1913. The decrease was due mainly to the lateness of the spring. Reports from the new Tolovana district have varied, but recently returned miners are hopeful.

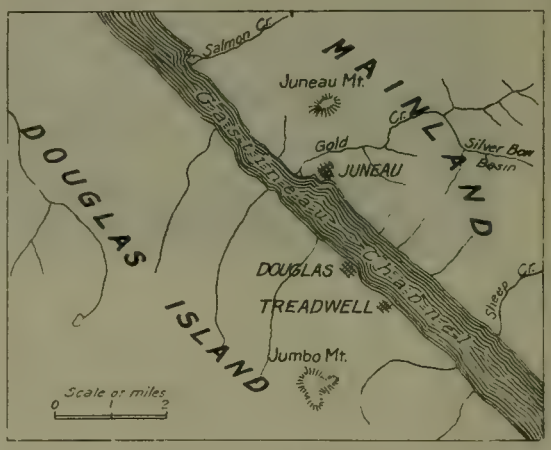
On Fish creek, into which Fairbanks creek empties, there is a little mining being done. McRae & Co. are using a 40-hp. plant to operate a slip scraper in the shallow ground on First Chance creek, a tributary of Fish creek. Carlson & Co. are working on the upper end of No. 1 Above, where the ground is 28 ft. deep. Taylor & McLeod are working on No. 2 Above. Each outfit is employing four men. On Monte Cristo Pup, a tributary on the right limit to Fish between No. 11 and No. 12 Above, J. C. Murphy is working in a small way. Fred Harkins is working, with a couple of partners, on Pearl creek, another Fish tributary. He is ground-sluicing shallow gravel.

Juneau

An interesting general review of the Juneau district mines for 1914 is given in the *Alaska Daily Empire* of December 31. The Alaska Gastineau company's dam at Salmon creek was finished to 165 ft. height and 720 ft. length, using 52,000 cu. yd. of concrete. It will hold 19,000 acre-feet, and now contains 13,000 acre-feet. Both power plants are working. At the mine outside construction is complete. Boarding house, dining room, club house, machine shop, and compressor plant can accommodate 500 men. The compressors have a capacity of 5000 cu. ft. of air per minute. The Sheep Creek tunnel was completed, rails laid, and trains are now running through to the crushing plant. The electric locomotives weigh 18 tons, and the cars will carry 10 tons each. The old Perseverance mine is connected with this tunnel by ore ways 2000 ft. apart, open at each level for ore. Eight levels in the main mine, 200 ft. apart, are all open to the surface in Icy gulch. Every modern underground convenience has been installed. The coarse-crushing plant is finished and has a capacity of 20,000 tons per 24 hours. As the ore cars come from the Sheep Creek tunnel, they are discharged four at a time in electrically operated tipples. The ore passes over grizzlies to 36 by 48-in. jaw-crushers, further screened, and finally crushed to 2 inch in two No. 8 K-type gyratory crushers. The ore falls into an underground storage bin of 10,000-ton capacity. Conveyors then carry it to the mill. This contains motor-driven rolls 54 by 72 in., elevators, screens, and concentrating tables. The plant will treat a minimum of 6000 tons of ore per day.

At the Alaska Juneau property considerable development has been done. A 4000-cu. ft. Ingersoll-Rand compressor is being installed. The site for the large mill was cleared, and necessary buildings erected. Three 9-ton electric locomotives will haul ore to the new mill. The 50-stamp mill is ready. It will crush ore through a ¼-in. screen. One 6-ft. Chilean mill will regrind the pulp from each 10 stamps. An 8-ft. Hardinge mill will regrind concentrate prior to amalgamation. Wilfley tables are to handle coarse material from the stamps.

Owing to the financial condition of the Ebner company, little



MAP OF JUNEAU DISTRICT.

is being done, but a number of men have been extending the main adit, which is now over 8000 ft. long. The mine is one of considerable importance.

The Jualin Alaska Mines Co. contemplates the development of its mine to a capacity of 1000 tons per day. The claims are on the north shore of Berner's bay. As the Company is financed by French and Belgians, work has been curtailed owing to the war. A 5½-mile tramway was constructed from the mine to the wharf on the bay, 4000 ft. of flume and 4500 ft. of pipe was laid for the power plant, a 450-hp. air-compressor installed, and an air-pipe laid to the mine, a distance of 9000 ft. Four sets of Diesel engines will drive generators on the bay when the water supply is low. The mine shaft is to be sunk to 335 ft. Diamond-drilling has been done. The mine is a wet one, and pumps are necessary, but a drainage adit is to be finished, its length being 8000 ft. About $450,000 has been spent to date. Bids were called for mill erection just prior to the outbreak of the war. H. G. Young is general manager.

Fifty miles north of Juneau, in the Berner's Bay district, the Kensington Mining Co. has 70 claims. The ore occurs as a stockwork or a number of veins in diorite, and is similar to that of the Treadwell mine. A cross-cut has been driven over 5000 ft., and three stockworks were cut 2000, 2500, and 5000 ft.

from the portal. Lateral work sampled shows an average of $4 per ton. Plans are under way for ore treatment.

The Eagle River Mining Co. of Georgia is operating 25 miles north of Juneau. Since 1903 the 20-stamp mill has produced over $500,000. The property is fully equipped. The lode formation consists of small rich shoots in black slate. In the Eagle River mine eight of these were mined formerly, although there was considerable faulting. Two years ago these workings were abandoned and a lower adit has been driven 2000 ft. to cut the formations beyond the faulted area. During the past summer the first was cut at 700 ft. depth, showing similar ore and gold content as above. The mill is working again on $20 ore.

Monthly yields of the mines on Douglas island are published frequently in the *Press*, and the regular character of operations is well known to readers of this journal. At the Treadwell mine, work on the 2100-ft. level at the central shaft has been continued. This will facilitate operations in this mine, the 700-Ft. Claim, and the Mexican. The central shaft and crushing plant of 4000-ton daily capacity started during the year. The 300-stamp mill has been equipped with two 500-hp. motors, and the 240-stamp mill will be provided with electric drive in the spring.

At the United company's Ready Bullion mine, a new incline shaft is being sunk to open it 200 ft. below the 2200-ft. level. This shaft is to be kept in the foot-wall slate, the old one being in the greenstone hanging wall. The 700-Ft. Claim is being developed at 2100 ft. The 700-Ft. mill was increased to 150 stamps, and the Ready Bullion 120-stamp mill is also to be increased to 150 in the spring.

At the Mexican mine, the lower ground is being opened by drifts from the 700-Ft. Claim of the United company. No changes were made to the mill.

The new 4740-cu. ft., or 50-drill capacity, Ingersoll-Rand compressor was started at the Alaska Juneau on January 8. It weighs 60 tons, and is rope driven from a 750-hp. General Electric motor. It was erected in 21 days, in charge of Otto Koehler.

ARIZONA

Gila County

It is stated that the International smelter being constructed at Miami may be blown in as early as next April. The output is estimated as 55,000,000 lb. copper from the Miami, and 75,000,000 lb. from the Inspiration. When at capacity the net earnings should be between $1,250,000 and $1,500,000 per year. The Anaconda company of Montana controls the International.

On account of a non-union boilermaker being employed at the Inspiration mine, 25 unionists 'downed tools' on January 12. This action was followed by about 500 tradesmen at the concentrator and smelter. It is also stated that a demand has been made for the restoration of the 10% cut made in wages early in August. Meetings were held and some men wanted the Miami employees to walk out. The secretary of the miners' union declared the strike irregular, and all miners must go to work. C. E. Mills, general manager for the Inspiration company, made the following statement to the employees on the wage dispute: "In view of the present copper situation and the general desire for more pay, I am authorized by the Company to say to you, although it is not yet in the producing stage, that the wages the Company pays its employees are of necessity governed by the copper conditions on which the producing companies of the state base their wage rate. As a consequence, it has been the policy of this Company in the past to raise wages along with the producing companies, although it was at these times producing no copper and benefitting in no way from the increased price of the metal. This policy it expects to and will gladly maintain. All but late comers in the district will remember that the companies, on their own motion, twice raised wages in 1912 on account of the advance in copper prices. The average selling price of copper for the last month was 12 8c., the future price is uncertain, but there are decidedly hopeful signs, and the Company trusts that the past actions of the employing companies of the district will guarantee that the employees will get the benefit of any improvement in the copper conditions at the earliest date possible."

The New Keystone-Inspiration deal is the subject of considerable discussion in New York. A circular has been distributed by Carl Pforzheimer, a large holder of shares in the former Company, giving details of the value of the property. According to the engineer's report of 1912, drill holes and underground work developed 2,516,000 tons of 2.25% ore. Reports in 1911 show about 5,000,000 tons of oxide ore. As a reply to this note, the president, Samuel A. Lewisohn, states that the ore is mixed and difficult to treat. A 1000-ton mill and other plant would be necessary, and this would cost up to $1,250,000. Allowing for all charges, the net annual profit would be only $94,300, or 26c. per share. The Inspiration has 75,000,000 tons of sulphide ore, has raised $12,500,000, is erecting a 10,000-ton plant, and would make a profit of $4.18 per share. At the proposed rate of exchange of shares, Keystone shareholders would receive $9.29 per share in 20 years, instead of $1.82 in seven years if the mine is worked alone.

A vote taken by the Miami miners' union demanding the old rate of $3.75 per shift, against $3.40 at present, resulted in a decision to 'down tools' by a three-to-one vote. The properties affected are the Miami mine and mill, Inspiration mine and mill, and International smelter. Contractors' iron-workers are not affected. All plants are shut down.

Mohave County

The Tom Reed gold output in December was approximately $115,000. Mining below 1000 ft. is decidedly encouraging.—— The Copper Canyon mines have been visited by Henry E. Woods of Denver, R. C. Jacobson, and Anson H. Smith. The former is looking for molybdenite ores and is buying ore from this district. Copper and molybdenite occur together here.

Pinal County

The Kelvin-Sultana Copper Co. held a meeting in Chicago recently. It was decided to increase the capital to $5,000,000 by the addition of 2,000,000 $1 shares. Mine development is to be commenced from the Westfall shaft at 540 ft., to the south end of the property, cutting six veins. This cross-cut will be 2100 ft. long. The new 300-ton mill is to be prepared for resumption of work, and several additions will be made to the power plant.

CALIFORNIA

Amador County

The December output and costs of the Plymouth mine are estimated as follows:

		Per ton.
Tons of ore crushed	10,200	
Value of gold	$42,330	$4.15
Working expenditure	22,618	2.21
Development charges	5,051	0.49
Surplus over above expenses	14,660	1.45
Other capital expenditure	16,283	1.60

The South Jackson Mining Co. states that prospecting has been disappointing on the 500 and 345-ft. levels. Quartz lodes were opened, but they were valueless, save 30 ft. of $3.80 ore 30 in. wide. Prospecting cost $104,000, and at 345 ft. there is 100 ft. of ore 11 ft. wide, not enough to justify a plant. The property is to be closed.

Butte County

The suit of the Forest Service against the Oroville placer mining claim at Forbestown last week was heard at Oroville. A patent is being resisted on the ground that the claim does not contain placer deposits, and further that $500 worth of work has not been done. The answer alleges that the ground

contains placer deposits, some of it prospecting as high as 20c. per pan, that a legitimate discovery of placer gold was made there, and that the indications of a placer deposit are such that a person of ordinary prudence would be justified in expending labor and means with a reasonable prospect for success in developing a paying mine. It also alleges that over $500 was expended in assessment work. W. A. Merrill, of the Forest Service, stated that he found quartz, but no gravel. His examination of the ground occupied four hours. E. P. Gleason made a similar statement, but also said there were quartz deposits. The cross-examination of these witnesses brought out some peculiar methods of inspecting the claim. John M. McIntosh, George White, R. A. Grasse, and E. Kloss also declared that the ground was more valuable for quartz than placer mining. A warm discussion ensued over the meaning of what placer ground and placer mining was. These witnesses ended the case for the Forest Reserve. H. P. Stow, formerly with the Gold Bank company at Forbestown, testified that the ground was a placer area. John Mill, H. Beik, C. K. Colvin, W. Lennon, H. E. Vail, N. Riley, J. C. Labadre, W. H. Ladnes, and C. C. Belding also gave similar views. M. J. Cooney, the principal locator of the ground, was the last witness, and said the right of location of the Oroville placer claim was justified by the fact that some of the area at least is old placer ground. All of the testimony given will be referred to the Commissioner of the Land Office for a decision.

Eldorado County

The Rising Hope gravel mine has been developed during the past three years, and a 150-ton mill has been ordered from the Placerville foundry. Charles M. Henson is superintendent, and G. W. Englehardt represents the New York people supplying money for the property.

San Diego County

The Julian mining district is 60 miles northeast of San Diego, at an elevation of 4250 ft., and placer gold and gold quartz was found there in 1870. Rich ore was mined here in the early days of the field, and the total output to date is said to be several million dollars. The deepest mine at the present time is the Owens, which has been opened to 350 ft. San Diego people are trying to increase the interest taken in the area, and think that numbers of mines are worth reopening.

Shasta County

Zinc ore is to be sent to Oklahoma smelters from the Friday-Lowden mine by the Mammoth Copper Co. A sorting plant is to be erected, and the high-grade zinc ore separated from the copper ore. Other mines in the district have large quantities of similar ore, which is a nuisance in smelting. The Company blew in another blast-furnace at Kennett last week, making three in operation. The Company has sent 28 ingots of copper to the Panama-Pacific Exposition, besides other exhibits.

Sierra County

Very rich gold-bearing quartz, heavily mineralized with arsenical pyrite, has been cut on the bottom level of the North Fork mine near Forest. George F. Stone is manager.

Tulare County

There are signs that the old White River district, near Terra Bella, may have a revival, as shown by the transfer of several properties. The Bald Mountain, Josephine, and other claims are to be reworked. Prospectors are looking for placer ground. Six miles south, the Grizzly mine is keeping a 5-stamp mill at work.

Tuolumne County

The Black Oak shaft at Soulsbyville is to be deepened from 1700 to 1800 ft.——The old Confidence mine is to be reworked by a new company. An adit will be driven to open the lode. T. G. Winwood is in charge.

COLORADO

The Colorado Metal Mining Association held its annual convention at Denver on January 11. Bulkley Wells, of Telluride, is president, and the meeting was attended by representative mining men, Governor Ammons, and Governor-elect Carlson. Three topics of principal interest to mining men were the organization for concerted opposition to the leasehold bills now pending before Congress, the amendment of the mining taxation law which has been a sore point for several years, and the probable consolidation of the various departments of the state government whose activities are concerned with mining, so that their work will be made of greater practical value. The Association, at the suggestion of the state mining commissioner, T. R. Henahan, planned a silver convention to be held at Denver during the current year. The object of the meeting is to fix a standard price for silver and to arrange for an international convention at which free coinage of silver will be urged on all the civilized nations of the world. Officers chosen at the directors' meeting were Bulkley Wells, president; George O. Argall, Leadville, first vice-president; Horace F. Lunt, Colorado Springs, second vice-president; Richard Roelof, Cripple Creek, third vice-president; John M. O'Connell, Denver, secretary; and A. M. Collins, Creede, treasurer. Committees on finance, publicity, legislation, and mining and milling were also appointed.

San Miguel County

The Tomboy mine in December produced 12,625 tons of ore, yielding $50,500 bullion and $34,500 in concentrate shipped. The mill worked 21 days. The profit was $27,860.

Teller County (Cripple Creek)

The Cripple Creek Times estimates the output of the district in 1914 as 980,239 tons, yielding $13,551,932. The output to date is $337,338,672.

The very rich telluride ore opened in the Cresson mine was at 1200 ft. depth. This level showed ordinary grade ore

CRESSON MINE, CRIPPLE CREEK.

for a length of 300 ft., and from 15 to 100 ft. wide. The system of mining was by the pillar method, without square sets. Lateral drifts were driven about 20 ft. apart, the intervening ground being ore. Stoping is extended over these drifts, and in cutting out for an ore-chute a streak was cut and followed, resulting in the discovery of a vug or cave, 15 by 20 by 40 ft., rich in sylvanite. Up to the beginning of the current year 1400 90-lb. sacks of very rich, and 1000 sacks of over $1000 ore had been mined.

IDAHO

Shoshone County (Coeur d'Alene)

The Marsh company, at Burke, is sinking its shaft from

700 to 900 ft. The electric hoist is now ready in the new station at 700 ft. At the bottom of the Hypotheek shaft, 50 ft., a crosscut has passed through 20 ft. of ore, 3 ft. assaying 12% lead, 3 oz. silver, and $1.80 gold, the balance being lower grade, but profitable to work. Development in the Nabob is extremely encouraging.

Discussing the past year's work of the Coeur d'Alene with the *Spokesman-Review*, Spokane, Washington, Stanly A. Easton, of the Bunker Hill & Sullivan company, said: "Estimates of a preliminary character, but of authoritative source, indicate that while the 1914 profits of the Coeur d'Alene will be badly cut into because of the demoralized condition of the metal markets, yet the production exceeds even the former high mark of 1913. The output that year was reported by the government at 148,370 short tons of metallic lead, and for 1914 there is now estimated the remarkable production of 171,730 tons of lead, 13,566,000 oz. of silver, 24,600 tons of zinc, and 21,201 tons of copper. The Coeur d'Alene lead production in 1913 was about 36% of the domestic yield of the United States. The district suffered less industrial depression than any other mining field in the northwest, and if a better market had prevailed the production would probably have been still greater. During the last four months of 1914 many of the larger properties voluntarily curtailed their output by confining operations to the poorer grades of the ore, and the mines at Mullan were practically all closed. This large production would not be so encouraging were it not for the fact that much of it comes from ground hitherto unproductive, in new territory, and the deep development of all of the older properties is of the most satisfactory character. It may, therefore, be predicted with every assurance that the output of the district for several years to come will certainly be up to the present standard of quantity if there is a market, and for many years to come the district will be an important centre for the production of these metals."

MISSOURI

Jasper County

Production of the Joplin and other districts in the second week of 1915 was as follows:

Mineral.	Pounds.	Average per ton.
Blende	8,960,730	$48.28
Calamine	484,660	25.53
Lead	1,437,640	46.71

The Granby Mining & Smelting Co. has made its first purchase of zinc ore for the new Rose Lake, Illinois, smelter, which has a capacity of 400 to 600 tons per week. This plant was described by E. H. Leslie in the *Press* of September 12, 1914.——Considerable work is under way at the old Hoo Hoo mine at Joplin. Sheet-ground has been opened at 180 ft. by three drifts. The mill is of 200-ton capacity.——The McKinley company has started drilling west of Duenweg.——A model showing workings of a Joplin mine has been made for the Panama-Pacific Exposition by Ruhl and Shanklin.——The Oronogo Mutual mill has been driven by steam, gas, and electric power, but it has been decided to have all machinery driven by motors.——The Hornbrook ore, northeast of Joplin, occurs at a depth of 200 ft. and in soft ground, which is the only instance in the vicinity except one other. A 250-ton mill is in full operation.

NEVADA

Esmeralda County

The Western Ore Purchasing Co.'s sampler, at Goldfield, has been overhauled and is ready to receive ore. The plant is entirely automatic.——On March 1 the Jumbo Extension company will pay 5c. per share, or $62,500. The total to date is $222,158. The November return was $124,900, contained in 1599 tons of ore, giving $96,375 net. The December net yield was about $100,000. Development continues to be excellent.

The Florence mine produced 200 tons in December. A winze below 1750 ft. in the Atlanta has opened 3½ ft. of $75.80 ore.

Humboldt County

A rise above No. 4 adit of the Antelope Springs mine has opened 3 ft. of zinc ore.

The new district of Haystack, 8 miles west of Jungo, on the Western Pacific line, is showing fair activity, and small plants are contemplated to treat the free-milling ore. Lessees on the Haystack Mining Co.'s ground are opening good ore.

The Rochester Mines Co. held its annual meeting at Lovelock's last week. L. A. Friedman was elected president and general manager, also W. C. Pitt vice-president, H. J. Nurrish secretary, and R. Nenzel assistant secretary. Directors are L. A. Friedman, J. P. O'Brien of San Francisco, R. Hartley, W. C. Pitt, and Samuel Platt. The mill will be finished early in February, but the power will not be ready for two weeks later.

The Seven Troughs Coalition quarterly report shows that 1114 tons of ore was mined, worth $135,576. Amalgamation recovered 82.78%, and concentration, 10.40%, a total of 93.18%. The net value was $125,000. Rich ore is still showing at 1300 ft. A 600-hp. Fairbanks-Morse gasoline hoist is being erected.

Lincoln County

At the receiver's sale of the Day Bristol mine at Pioche, Eastern shareholders of the Bristol Consolidated Mining Co. purchased it for $99,200, which is the amount of indebtedness. The various claims yield copper, lead, and silver ores.

Nye County

Manhattan is considerably elated on account of the Tonopah Mining Co.'s deal to examine the White Caps property and buy it if satisfactory.——The new Muskett and Wittenberg plant on the Big Pine is doing excellent work. The tube-mill has shown that it can crush 250 tons of ore per day. A conveyor belt has been installed to discharge the overside from the grizzlies to the dump, and has reduced labor charges. A revolving trommel will take the place of the grizzlies.

Five mines at Tonopah last week produced 9148 tons of ore worth $190,624.——The Tonopah company's output in December was $163,525 from 12,540 tons, with $68,260 profit.——A fire service costing about $10,000 is under installation at the Extension.——The Nevada-California Power Co. is erecting three 2500-kw. transformers at its sub-station at Tonopah. These will take the place of 10 old ones.

UTAH

Beaver County

Placer mining is attracting considerable interest in this county. A California syndicate, with E. E. Lindsay in charge, has located 640 acres of ground on South creek, and careful sampling gave an average of 60c. per cu. yd. to a depth of 20 ft. A modified system of dredging is proposed.

Juab County

A report of the Lower Mammoth company shows that 728 tons of silver-lead, 336 tons of zinc, and 531 tons of copper ores were shipped, valued at $9996. Lessees produced 1096 tons of this amount. Including assessment, the net revenue was $23,644. Cash on hand at December 31 was $745.

The annual report of the Iron Blossom will appear in another issue of this journal under 'Company Reports.' The Company will pay 10c. per share, or $100,000, on January 25, making $2,270,000 to date.

The report of the Tintic Central Mining Co. for 1914 shows that development amounted to 542 ft. at a cost of $9.31 per foot. This was done on the 870-ft. level. A rise opened a large shoot of low-grade quartz, which contains pockets of

good ore, and a streak of lead-silver parallel with the fissure. The fissure will be further prospected. Certain claims have been leased.

New rolls are now working in the Knight-Christensen mill at Silver City.——Rich gold is being mined at 600 ft. in the Dragon Consolidated, worked from the Iron Blossom mine. A diamond-drill is working at 1900 ft. depth.——About 60 lessees are at the Eureka Hill and Bullion Beck.——Eight inches of rich silver-lead ore has been cut in the Yankee Consolidated, and is probably an extension of the shoot in the May Day.

PIUTE COUNTY

Ten miles from Marysvale is the Wedge Gold Mining & Milling Co.'s property, under lease to J. V. Sargent. Some very rich gold-silver ore has been cut at a depth of 85 ft. The ore is a quartz with a high percentage of manganese in rhyolite cut by porphyry dikes.

SALT LAKE COUNTY

The Montana-Bingham mine has been leased to S. T. Parr and C. B. Ferlin, well known at Bingham. Not less than 100 ft. of work must be done monthly in the main tunnel.

WASHINGTON

Profits made by companies in the 'Inland Empire' district of this state, Idaho, and British Columbia, were as follows in 1914:

Companies.	1914.	1913.	Total to date.
British Columbia Copper	.....	$ 88,756	$ 704,155
Bunker Hill & Sullivan, Ida.	$ 981,000	817,500	15,710,250
Caledonia, Idaho	166,329	.....	218,329
Con. Smelting of Canada	468,016	464,352	1,948,261
Federal, Idaho	600,000	720,000	14,265,545
Granby, B. C.	448,850	899,911	5,100,893
Hecla, Idaho	220,000	320,000	3,190,000
Hedley, B. C.	300,000	320,000	1,524,000
Hercules, Idaho	3,000,000	1,500,000	8,500,000
Inter. Coal & Coke, B. C.	30,000	120,000	946,000
Kendall, Idaho	30,000	.....	1,505,000
Knob Hill, Washington	.....	25,000	70,000
Le Roi No. 2, B. C.	.....	43,200	1,567,720
Snowstorm, B. C.	.....	45,000	1,124,640
Standard, B. C.	475,000	650,000	1,550,000
Stewart, Idaho	773,976	402,435	1,176,411
Success, Idaho	.....	90,000	930,000
Totals	$7,493,171	$6,506,154	$60,031,204

FERRY COUNTY

At a vertical depth of 250 ft., a cross-cut from the intermediate level of the Knob Hill, at Republic, has cut 4 ft. of $27 gold ore. Shipments of ore are to be increased, according to the manager, J. W. Beckett.

OKANOGAN COUNTY

(Special Correspondence.)—A new compressor and other plant has been added to the Golden Zone equipment. The mill is treating 30 to 40 tons of ore per day, yielding $150 to $200 in gold concentrate.

Conconully, January 16.

CANADA

BRITISH COLUMBIA

The Granby Consolidated produced 21,951,449 lb. of copper in 1914, of which 12,331,332 lb. was from the mines at Phoenix and 9,620,117 lb. from Anyox. The silver production for the same period was 357,752 lb. and gold 27,879 ounces.

ONTARIO

Five inches of 10,000-oz. ore has been cut at 530 ft. in the Temiskaming, an extension of the Beaver vein.——The annual report of the Wettlaufer Lorrain Silver Mines Co. shows that the revenue was $17,531, and profit $5164. No mining was done during the year, and the workings are full to No. 4 level. The outlook for reopening is remote, but the plant is kept in good order, and a caretaker operates the electric mine pump. Examinations have been made of other properties, with generally unsatisfactory results. The credit on hand is $109,913.——On March 15 the Kerr Lake company will distribute $150,000, making $5,670,000 to date.——The Dome mine produced 23,090 tons for $81,660, or $3.53 per ton, in December. During 1914 the total output was $1,065,629 from 219,609 tons.

Including the distribution on January 28, the Hollinger company is now paying 20c. per share per month, or $120,000, against 15c. or $90,000 previously.

MEXICO

SONORA

A special train from El Tigre to Douglas carried 128 bars of bullion, 146 sacks of gold precipitate, and two cars of concentrate from the Lucky Tiger Combination company's mine on January 15. These products contained 700 oz. gold and 225,000 oz. silver. The train, the first shipment in seven weeks, was accompanied by L. R. Budrow and J. W. Malcolmson. There were no important incidents on the trip.

Forty-four cars of concentrate, part of the Moctezuma Copper Co.'s accumulations due to rain and revolution, arrived at Douglas on January 14 from Nacozari. Empties are being sent south for further shipments. First, and especially second-class mail to Nacozari, has been held up for weeks.——The Santa Rosa mine, near Cabullona station, sent a car of copper ore across the border on January 14.

When Nacozari is to be attacked by the Maytorena or Villista forces is doubtful, but they have over 600 men and four cannon marching on the town. The garrison may fight, but surrender is to be expected.

TAMAULIPAS

Notwithstanding the present unsettled conditions prevailing in this district, the November shipments of crude oil from Tampico to the United States shows a steady increase over the same month of the preceding years. During November 1,106,248 bbl. was shipped, compared with 1,028,068 bbl. during November 1912.

NICARAGUA

The Tonopah Mining Co. of Nevada has issued a statement to the effect that it has an option on the property of the Panama Mining Co. in Nicaragua, and has until the first of February to decide whether it will take the property or not. In case the option is exercised, a new company, controlled by the Tonopah Mining Co., will be formed to take title to the property and operate it, and the stock of this new company issued to pay for it. Forty per cent of the stock of the new company will be turned over to the Panama Mining Co. to be disposed of as its officers and stockholders may determine. It will be noted that under this arrangement, if the option is exercised, the Tonopah company buys the property and does not buy the stock of the Panama company. A circular has been issued stating that the property will be taken over on January 28.

The former president of the Panama Mining Co., Rolando Kuehn, and a large shareholder, filed a suit in the United States district court at Philadelphia against the Panama Mining Co. and its officers, and the Tonopah Mining Co. of Nevada and its officers, asking for an injunction restraining a conveyance of the property of the Panama company to the Tonopah company with the forming of a new company to be known as the Eden Mining Co. Kuehn charges the directors of the Panama company with having been guilty of fraud and neglect. He also alleges that no accurate return of the Company's accounts was made. Other objections to the deal were made by the plaintiff.

PERSONAL

HENRY E. WOOD was in San Francisco

ARTHUR THACHER is visiting New York.

L. C. GRATIN was in New York last week

JOSEPH CLENDENIN has been in California.

WALDEMAR LINDGREN was in New York last week

H. FOSTER BAIN and CHARLES JANIN have gone to New York.

J. V. N. DORR has gone to Denver and will remain there about a month.

C. WILLARD HAYES is in Washington, D. C., and expects to go to London soon.

ARCHER WILMOT HENDRICK has been elected president of the University of Nevada.

T. A. RICKARD was expected to arrive in New York on the *Lusitania* on January 22.

SUMNER S. SMITH, government mine inspector of Alaska, has returned to the territory.

M. N. COLMAN is now mill superintendent of the Atolia Tungsten Mines, Atolia, California.

R. C. STICHT, of the Mt. Lyell mine, left for Tasmania on the *Ventura* on January 19. He has been on a long visit to the United States.

J. K. TURNER, consulting engineer for the Jumbo Extension Mining Co., has left Goldfield for Johannesburg, California, for a business trip of several days.

W. MOTHERWELL, who has been experimenting with flotation processes at the Moctezuma Copper Co.'s mill, Sonora, has finished his work and is at Douglas, Arizona.

GEORGE W. GOETHALS was the guest at a luncheon given by the Western Society of Engineers and the Chicago Engineers' Club on January 22, at the La Salle hotel, Chicago.

BARTLETT L. THANE, general manager for the Alaska Gastineau Mining Co., has been called to Seattle to testify in the suit brought against the Company by Stanly Byers for $90,000.

C. A. FILTEAU, who was formerly with the Colorado Mining Co., Manila, sailed from New York on January 13 for Peru, where he will assume the management of the Inca Mining & Development Co. at Santo Domingo, in the province of Carabaya.

Obituary

EDWIN HAMMOND MOWER, 44 years old, died at Joplin on January 12. He was largely interested in Missouri mining concerns.

HANS VUNDER, superintendent for the Alta Consolidated Mining Co. at Alta, Utah, for the past four years, died recently, at the age of 42 years, from ulcers of the stomach. He had been a resident of Alta since 1887, and leaves a widow and five children.

EDWARD WARNE, 53 years of age, superintendent and master mechanic of the Franklin company's mill, Michigan, and in the company's employ for 34 years, died two weeks ago. He was an authority on milling methods, and highly esteemed in the copper country.

Mrs. M. A. PARR, principal owner of the Mineral Zone mine at Elk City, Idaho, died on Nov. 25 from heart failure. Mrs. Parr was well known among mining men. She kept a small hotel, and grub-staked many a miner who was in difficulties. It is pleasant to record that this brought its own reward, since she died possessed of extensive mining holdings.

THEODORE ARMSTRONG died, on January 5, at his home in Chestnut Hill, Philadelphia. He was born in New York in 1841 and was one of a family of seven children. His ancestors had been prominent soldiers in the Revolutionary War and following their traditions Mr. Armstrong and his brothers served in the Union Army through the Civil War. At the close of the war he was appointed to a position in the accounting department of the Internal Revenue Service and a short while afterward was appointed chief accountant of the Pennsylvania Salt Manufacturing Co. at its plant at Natrona, Pennsylvania. Seven years later he became chief auditor of the Philadelphia offices and he was promoted to secretary. By faithful application to duty he rose to treasurer, vice-president, and finally president of the Company in 1888. He was also president of the Wedge Mechanical Furnace Co. and was prominent in business affairs in Philadelphia. In various industrial organizations he was an able and progressive executive and the success made by the companies with which he was connected is in large measure due to him alone. He was a miner of wide interest and a prominent member of such diverse organizations as the Union League Club, the Society of Chemical Industry, the National Association of Manufacturers, the Historical Society of Pennsylvania, the Academy of Fine Arts, and the Ancient Order of United Workmen. He will be keenly missed in the public life of Philadelphia.

BARTON SEWELL died at his home in New York, on January 7, after an illness of a few months. Mr. Sewell was born in 1847 and at the age of fifteen was a drummer boy in the Union Army in the Civil War. After the war he engaged in the dental supply business in Chicago and by the early seventies he had attained so strong a position in the metal industry as to organize the Chicago Smelting Works. Later this was consolidated with the Chicago & Aurora Smelting Co., and about 1888 Mr. Sewell sold out his interest in this Company and organized the National Smelting & Refining Co., at Chicago, of which he was president. About 1891 this Company was purchased by the United Smelting & Refining Co., which needed a refinery in connection with its smelters at East Helena and Great Falls, Mr. Sewell becoming general manager of the United and retaining the presidency of the National. About 1899 he joined with H. H. Rogers, Leonard Lewisohn, F. L. Underwood, and E. W. Nash in forming the American Smelting Co., which two years later joined in a consolidation with Daniel Guggenheim's Sons to form the American Smelting & Refining Co., since popularly known as 'the Guggenheims.' When the American Smelting & Refining Co. was formed he became vice-president and a director of this organization and remained so until the time of his death, holding a similar position in the American Smelters Securities Co. when that corporation was formed. He was active in the formation of the United Lead Co., and was its first president, though not connected with it at the time of his death. During recent years he had chiefly devoted his energies to the Braden Mines Co., of which he was president. He was also a director of the U. S. Zinc Co. Besides his wife, two sons, William B. and Fred W. Sewell, survive him. He was an active factor in the manifold activities of the great organizations with which he was connected and his loss will be keenly felt.

Schools and Societies

The Columbia section of the A. I. M. E. will meet at Spokane in February. Mining laws, taxation, mining and milling methods are suggested by the committee as desirable subjects for papers and discussions.

A 'Caterpillar school' is to be held at Stockton, California, January 18 to February 13, by the Holt Manufacturing Co. F. L. Peterson, formerly assistant professor of farm mechanics at the University of California, is in charge of the course, by which full instruction will be given in the use of the Caterpillar gas tractor. This machine is useful in hauling mining or farming supplies. The tuition fee is $25 for the term.

THE MARKET PLACE

Weekly Summary of Prices of Shares and Metals

Metal Prices

San Francisco, January 21.

Antimony	15 —15¾
Electrolytic copper	14 —14¼
Pig lead	3.95— 4.00
Quicksilver (flask)	$52 50
Spelter	7 — 7¼
Tin	34½—36
Zinc dust, 100-kg. zinc-lined cases	9

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, January 21.—Copper is strong and advancing at 13.53c., lead quiet and weak at 3.70c., and spelter strong and advancing at 6.13c. per pound.

SILVER

Below are given the average New York quotations in cents per ounce, of fine silver.

Date.		Average week ending	
Jan. 14	49.12	Dec. 9	49.91
" 15	49.00	" 16	49.83
" 16	48.75	" 23	48.66
" 17 Sunday		" 30	48.65
" 18	49.00	Jan. 6	48.65
" 19	49.00	" 13	48 98

June	59.03	56.43	Dec.	57.73	49.27

The silver market has been very steady. On January 16 the 'Shinyu Maru' took $123,190, or 250,000 oz. to the Orient. The Cobalt district of Ontario shipped 470,231 oz. last week to England, the Nipissing contributing 406,663 oz. The Indian Bazaars have given a little support to the market, but China is the mainstay at present. Stocks of metal in London at the end of 1914 were worth £1,400,000, or 14,500,000 oz. Pixley & Abell's 'Annual Circular' has been published, and should be secured by silver producers. The average price of bar silver in London in 1914 was 50.62c. per ounce, the range of prices being 11.25c., and in New York, 54.8c. Stocks held by the Bazaar in Bombay and Shanghai amount to about 70,000,000 oz. Imports into the United States were $25,331,000, and exports $50,500,000. Mexico supplied $14,186,000, and Canada, $5,657,000 of this.

LEAD

Lead is quoted in cents per pound or dollars per hundred pounds, New York delivery.

Copper exports to the end of November were 757,261,120 lb., and with December estimates, a total of 790,000,000 for the year, against 857,000,000 lb. in 1913. Consumers say that at the present price there will be a tendency to increase production, and are doubtless holding off with their orders. Now that the Copper Producers' Association no longer furnishes figures there is no telling what stocks on hand amount to; but it is not probable that they are small enough to justify any increase in production, and Thomas F. Cole has stated that he sees no probability of an increase.

ZINC

June	5.00	4.84	Dec.	5.07	5.40

Exports of spelter in November were 12,747 tons domestic and 957 tons foreign metal. In 11 months the total was 46,486 tons, against 3564 tons in 10 years to the end of 1912, when the total was 45,119 tons.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Week ending			
Dec. 24	53.00	Jan. 7	51.50
" 31	52.50	" 14	50.00
		" 21	52.50

June	41.00	38.60	Dec.	40.00	53.10

The quicksilver market is stronger, enquiries coming from foreign sources for supplies.

METAL PRICES IN FRANCE

According to a consular report of December 15, these were as follows: copper, 14.93c.; lead, 5.10 to 5.13c.; tin, 35.89 to 35.28c.; and zinc, 8.32c. per pound.

Transactions on the San Francisco Stock Exchange in 1914 were as follows: 62,167,554 shares valued at $16,103,664, against 41,300,952 shares and $14,411,153 in 1913. There were two periods of increased dealing, Tonopah and Goldfield stocks being the attraction.

MINING DECISIONS

Petroleum Lands—Executive Withdrawals

The President of the United States has no authority to withdraw petroleum lands from location and entry, pending the enactment by Congress of legislation in respect to such lands thought by him to be needful. The power to dispose of and make all needful rules and regulations respecting the territory and other property of the United States, including the lands thereof, is vested by the Constitution exclusively in Congress.

United States v. Midway Northern Oil Co. *et al.*, 216 Federal, 802 (California). May 29, 1914.

Sale of Mining Stock—Default Excused

A corporation agreed to sell B shares in a certain mining corporation, on specified payments, knowing that B did not have the money to buy the same himself, but would interest outside parties. Some good ore was developed, and B sought to make an examination accompanied by an engineer, which as a shareholder he was entitled to do; but the directors of A conspired to prevent the examination, so that B was unable to get his financial backers to raise the first installment of the contract price and defaulted in payment thereof. Held, that an action for specific performance would not lie, as B was in default on the first payment. Failure to enforce his legal right to examine the mine did not excuse the default.

Hobbs *v.* Davis (California), 143 Pacific, 733. October 5, 1914.

Severance of Surface and Underlying Minerals

A conveyance of underlying coal with the privilege of removing it, effects a severance of the right of the surface from the right to the underlying coal, and makes them distinct corporeal hereditaments; the presumption that the party having possession of the surface has also possession of the subsoil not being applicable after such severance. In such case the owner of the surface cannot by mere possession thereof gain prescriptive title to the coal beneath it, but it would be incumbent upon him to prove adverse possession of the minerals as such, independent of the surface. The claimant of mineral rights under a void deed with mere color of title, who fails to retain possession of the mine for the prescriptive period, but abandons it and moves to another state, he is barred from recovering same under a subsequent claim of prescriptive title.

McBeth *v.* Wetnight (Indiana), 106 Northeastern, 407. October 9, 1914.

Synopsis of New Mining Laws

Act of August 25, 1914.—Provides that the Secretary of Interior may make agreements with applicants for patents for oil or gas lands included within an order of withdrawal as to the disposition of said oil or gas, or proceeds from sale thereof, pending final determination of the title to said lands.

Act of July 17, 1914.—Provides that lands withdrawn or classified as containing phosphate, oil gas, nitrate, potash, or asphaltic minerals shall be open to location, selection, entry, or purchase under the non-mineral land laws—all patents to contain a reservation to the United States of deposits withdrawn and the right to mine and remove the same. Any person qualified to acquire reserved deposits may prospect and mine on such lands for same upon furnishing a bond to be approved by court and Secretary of Interior protecting and compensating owners of the land for damages.

Act of October 20, 1914.—Relating to disposal of Alaska coal lands.

MINERAL STATISTICS

The following data covering the year 1914, are from the U. S. Geological Survey.

Coal in Michigan

The production was about the same as in 1913, when it was 1,231,786 tons.

Coal in the Rocky Mountain States

Excepting New Mexico, all of these states showed decreases. Colorado suffered on account of labor troubles, and New Mexico supplied the deficiency. Hydro-electric power is a competitor of coal in Montana. The outputs are as follows: Colorado, 1,000,000 tons less than in 1913; Montana, decrease from 3,365,712 to 2,938,671 tons; New Mexico, increase of 15 to 20%, to 4,450,000 tons; Utah, decrease of 10%; and Wyoming, a decrease of 7%. Reduced copper production affected Montana and Utah.

Metal Yield of Washington

According to C. N. Gerry, this was as follows: gold, $558,000, decrease of 20%; silver, 253,000 oz., or —23%; copper, 737,500, or —23%; and lead, 202,487 to 65,000 pounds.

California Metal Production

The output of this state was as follows, according to Charles G. Yale: Gold, $21,138,500, an increase of $731,500; silver, 1,987,700 oz., an increase of 609,300 oz.; copper, 34,000,000 lb., a decrease of 560,000 lb.; lead, 6,484,000 lb., an increase of 3,514,342 lb.; and zinc, 2,107,000 lb., an increase of 1,050,000 pounds.

Arsenic Production

According to F. L. Hess, white arsenic from smelters was 1227 tons, worth $251,268, against 2513 tons and $159,236 in 1913.

Idaho Metal Production

The depression of the metal market that followed the declaration of war did not prevent Idaho mines from again making a record production of silver, lead, and zinc, and the value of the gold, silver, copper, lead, and zinc produced at these mines in 1914 was $24,141,000, against $24,149,049 in 1913. Details are as follows: gold, $1,344,559, a decrease of 17%; silver, 13,000,000 oz., an increase of 30%; copper, 5,500,000 lb., or a decrease of 4,000,000 lb.; lead, 345,000,000 lb., an increase of 9%; and zinc, 38,614,000 lb., against 23,173,953 pounds.

Oil Output a Record

The phenomenal increase which has characterized the growth of the industry during the past eight years was more than maintained in 1914, according to John D. Northrop. Preliminary estimates show the yield to be 292,000,000 bbl., compared with 248,446,230 bbl. in 1913, Oklahoma, California, and Texas showing the greatest increases.

Coal in the Mississippi Valley States

According to E. W. Parker, the following are the yields last year: Illinois, a decrease of 10% from 61,000,000 tons in 1913, hydro-electric power from the Keokuk dam affecting coal used for steaming; Indiana, a decrease of 10% after October 1; and Iowa, a decrease of between 500,000 and 1,000,000 tons.

Oregon Metal Production

According to Charles G. Yale, this was as follows: gold, $1,600,000, about the same as in 1913; silver, 126,000 oz., a decrease of 53,000 oz.; copper, 5000 lb., against 43,000 lb.; and lead, 41,000 lb., a decrease of 46,000 lb. Of the 175 producing mines in Oregon, 125 are placers of small size.

New Machines and Devices

Lighting Plants for Steam-Shovels

For night work in steam-shovel operations, adequate illumination is imperative, not only for the bank from which the shovel digs, but also around the shovels themselves, to permit the necessary inspections and adjustments and to afford safety for the workmen. Acetylene had been tried for this work at the Utah Copper Co.'s property, but proved troublesome, costly, and somewhat dangerous, so illumination by means of electricity was adopted.

The general illumination of the bank is furnished by a battery of powerful projector searchlights on the opposite side of the cañon from the property. To supply local illumination, about twenty incandescent lights were placed on each shovel. The current supply for these lamps proved quite a problem. One of the difficulties was due to the shovels being constantly moved about. To meet this difficulty, a reel

STEAM-SHOVEL WITH LIGHTING SET. THE ARROW SHOWS POSITION OF TURBO-GENERATOR.

which carried a semi-flexible cable was carried on each shovel. This arrangement gave considerable trouble, as the rocks rolling from one terrace to another would carry away wires or poles, and blasts would frequently throw rock that would damage the semi-flexible cables along the ground. Not only were such accidents costly on account of the replacements required, but shovels were frequently put out of commission due to all lights going out when a rock from a higher level crashed down through its feeder line. The problem was one of constant annoyance until in December 1913 the Westinghouse Electric & Mfg. Co. furnished the copper company with a 1-kw. general utility turbo-generator outfit. This set was mounted directly on the shovel, being fastened to the under side of the main shovel frame, as shown in the accompanying illustration, and was supplied with steam from the boiler furnishing steam to the shovel. The shovel with its little self-contained power plant was immediately freed from all interruptions caused by accidents to its supply of illumination. The turbo-generator outfits are now in use on seven shovels, making, it is claimed, a great saving in wire and time. One of these sets will operate an arc lamp and a few incandescents at the same time, or about forty 25-watt incandescents. Practically no attention is required for the set, and there are no delicate adjustments to make. Full rating is developed on steam pressures between 90 and 250 lb. A governor controls the speed and keeps it uniform. A fixed resistance furnishes voltage regulation, and a rheostat is provided to adjust the voltage when the number of lamps in use is varied. Hence, in spite of the abrupt changes in steam pressure and load that characterize shovel service, steady light is obtained.

Commercial Paragraphs

The *Caterpillar Times*, house organ for the HOLT MANUFACTURING Co., Stockton, California, contains numerous instances of the adoption of the caterpillar type tractor to agricultural purposes.

S. FLORY MANUFACTURING Co., Bangor, Pennsylvania, has published an elaborately illustrated bulletin devoted to the products of this Company which were used in the construction of the Kensico dam. This equipment included two 12-ton capacity cableways, two Flory tower moving hoists, nineteen Flory 75-hp. two-speed patented hoists operating traveling derricks on the dam and at the quarries and twenty-two Flory 11-hp. boom swingers for traveling derricks.

MESTA MACHINE Co., Pittsburgh, Pa., in Bulletin 0 and 1 are presented detailed descriptions of the rope drives and gas-engines manufactured by this Company. Rope drives are claimed to have many advantages over other types of drives and are especially adapted to heavy work. The catalogue is illustrated and contains considerable information on the subject. The gas-engines of the Company are built for all classes of service and for any fuel. Bulletin 1 contains a brief description of Mesta gas-engines together with information regarding their operation.

The PELTON WATER WHEEL Co., San Francisco, California, has recently issued a very attractive catalogue, Bulletin No. 8. This bulletin illustrates and describes the Pelton wheels which are particularly adapted to driving mining, sawmill, industrial, and other machinery, and to acquaint the prospective purchaser with a few of the types of Pelton wheels technically designated as standard. The bulletin is replete with illustrations and contains a large amount of information regarding the installation and operation of Pelton wheels for a wide variety of power purposes.

ALLIS-CHALMERS MANUFACTURING Co., Wilwaukee, Wisconsin, in Bulletin No. 1088, describes the distributing transformers manufactured by this Company. Among the features claimed for this transformer are three cooling surfaces in place of one as usually employed, a continuous natural circulation of oil, and a low operating temperature. The bulletin is fully illustrated and shows in detail the construction and operation of this type of transformer. Bulletin No. 1089 is devoted to the reversing motor planer drive. The motor as used for this work is automatically reversed at the end of the cutting and return strokes. In the design of this motor no effort has been spared to provide apparatus which will be the best for the particular character of the work to be performed. Bulletin No. 1090 is devoted to motor-generator sets. The motor-generator set is a convenient means of transforming or converting electrical energy from one form to another. For this purpose the Company manufactures a large variety of sets to meet the requirements of the many conditions obtaining in practice. The bulletin is fully illustrated and contains considerable general information on the subject.

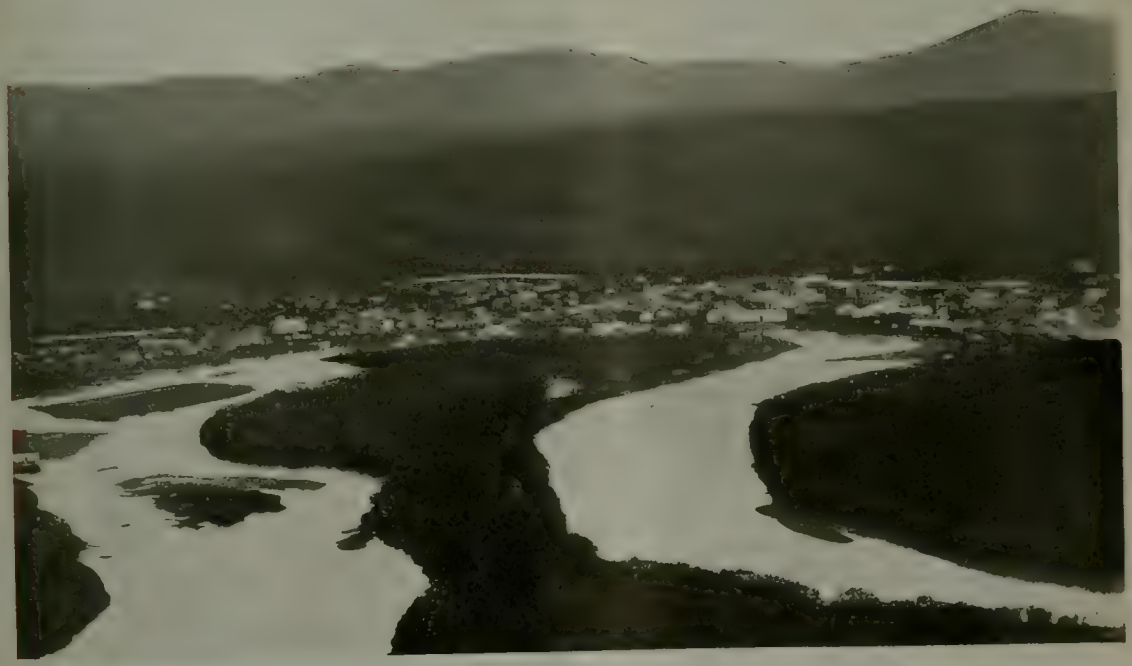
ITDITAROD was the scene of a gold discovery in 1909, and during the succeeding years the town of this name was established and foundations laid for a gold mining industry. Reports of the fabulous wealth of the district attracted prospectors and engineers from everywhere and the 'long tom' and sluice boxes were very much in evidence until the winter of 1911-12, when control of a large part of the ground was obtained by the Yukon Gold Company. The advent of the dredge marked a new era in Iditarod mining and the old time placer miner has been superseded in large part by buckets and ladder. The Yukon company obtained $734,000 during the past season from dredge operations at Iditarod. The situation in the district at the present is discussed in the current issue by Mr. Hurja.



PUMPING MACHINERY

High Efficiency must be carefully considered when pumping machinery is selected, but the importance of

Service is often overlooked. If two men must work for a half day each month repairing a twenty horsepower electric pump, the

Cost of Labor alone will be more than the saving made by a pump having 5% higher efficiency than one which would require no shutdown for repairs.

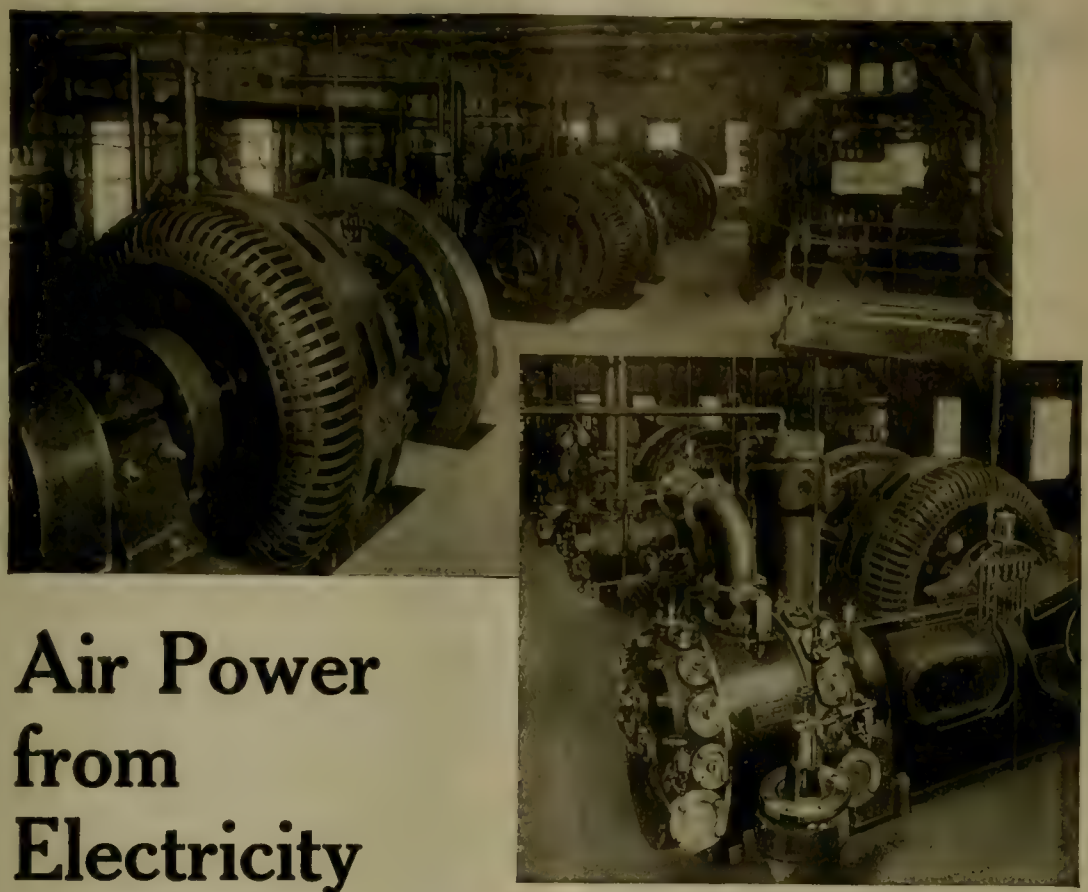
For Mine Service it is especially important to select equipment that will

Work Continuously with little or no cost for repairs.

Total Operating Cost is of more importance than high efficiency.

We have had experience with many kinds of pumping machinery and believe our engineers can be of service to you.

Hendrie & Bolthoff
MFG. and SUPPLY CO. DENVER, COLORADO



Air Power from Electricity

May Be Produced at Lowest Cost if You Select Sullivan "WN2" Direct-Connected Air Compressors

These pictures show three 2,000-foot Sullivan "WN2" two-stage air compressors, operated by synchronous motors mounted on the crank shaft. They formed a plant in Central Park, New York City, for supplying air to drills in the Catskill Aqueduct tunnel.

High volumetric efficiency — Low electric power input per foot of air compressed—Continuous operation, year in and year out, are among the advantages embodied in this Sullivan model.

Reasons include—

1. Corliss inlet air valves, providing large direct openings to the cylinder.
2. Very liberal area of discharge valves.
3. Total closure unloading valve of the non-choking pattern, with atmospheric relief valve on high pressure cylinder.
4. A heavy fly wheel to eliminate peak loads.

ARTICLES

THE MANGANESE INDUSTRY IN CALIFORNIA.
By Samuel H. Dolbear 172

California has been a purchaser of manganese ore for nearly fifty years. Of the early output a large part was consumed by chlorination plants. However, since the cyanide and other processes have practically eliminated this market, the ore at present being mined is used largely by local steel mills and dry cell manufacturers. Manganese ore is known to occur in 33 counties in California. The present status of the industry and the uses to which the ore is being applied are discussed.

COAL-DUST FIRED REVERBERATORY FURNACES 175

The use of coal dust as a fuel for reverberatory furnaces is being tried out at the Washoe smelter with satisfactory results. Details as to the operation of one of the furnaces is described.

THE INFLUENCE OF SLAG AND FUMES ON THE ZINC MUFFLE.
By O. Proske 176

A large amount of experimental work has been conducted under the direction of O. Proske on the influence of slag and fume on zinc muffles. The results of this experimental work are interesting and instructive. It was necessary to establish the absorption of zinc oxide by the clay and the combination of zinc oxide with the individual constituents of the clay. The investigation followed three lines of attack, namely, the diffusion of gases as influenced by pressure, temperature, and time.

IRON MINING IN MICHIGAN. *Staff Correspondence* 180

The total production of iron ore from the mines of the Marquette range during 1914 amounted to 2,463,973 tons. During the year 30 mines shipped ore. Production statistics of the mines are presented.

KAURI GUM DEPOSITS OF NEW ZEALAND.
By W. D. Hornaday 181

While little is known to the outside world of the kauri gum mining industry of New Zealand, it is nevertheless an important industry, and has a production since its beginning in 1853 valued at approximately $85,000,000. The present annual production is about $2,500,000. The manner of mining the gum is illustrative of the well known fact that many things are done differently in New Zealand from any other country on earth. Interesting details regarding the industry are presented in an instructive manner.

BLAST-FURNACE PRACTICE AT MOUNT LYELL, TASMANIA.
By Robert Sticht 183

The Mount Lyell company began operations in 1896 with three blast-furnaces, and later installed converters. This plant was enlarged to six blast-furnaces, and a second plant of five additional furnaces was later erected. The development of the present practice has been largely the outcome of years of experience in the treatment of the Mount Lyell ore. This development has been an interesting one, and is described by Robert Sticht, who has been connected with the Company for a number of years, and who brought to Mount Lyell a wide experience acquired in the treatment of ores in the United States.

CHILEAN NITRATE STATISTICS 185

The Iquique branch of the Nitrate Propaganda Association reports that the production of nitrate in November 1914 was 2,659,875 quintals, which is but little more than half of the production for the same period of the preceding year. Details as to production and value of output are presented.

FIRING BOILERS. *By Alexander M. Allen* 185

It is well known that boilers working in batteries, though of the same size and style, will not evaporate the same amount of water per hour. This is due in no small extent to the method of firing. The correct method for firing is the subject of this discussion.

DEPARTMENTS

DISCUSSION:

Bucket Elevators. *By William Seward Mann* 186
A method for overcoming difficulties in the use of bucket elevators.

Johnson Electric Furnace. *By Joseph Struthers* 186
An erratum in an article on the subject of electric smelting which appeared in our issue of January 2 is corrected by Joseph Struthers.

Solution Control in Cyanidation. *By A. W. Allen* 186
An answer to Haral Layng's contribution to the discussion of cyanide solution control, which appeared in our issue of October 17, 1914.

Precision of Thought. *By T. A. Rickard* 187
Attention is called by Mr. Rickard to the inconsistencies in the use of verbs as employed by the American Ambassador in a recent note to the British government.

CONCENTRATES 188

MINING IN THE FAR NORTH.

The Iditarod District—Dredging and Placer Operations. *By Emil Edward Hurja* 189
Mining in the Iditarod district during the past few years has undergone a change and small-scale operations, as conducted by the individual prospector and miner, have given place to the wholesale operations of the dredge. Mr. Hurja, in the present article, presents the status of the industry today with details as to operations which are at present being conducted.

A. W. Allen, Charles Janin, Leonard S. Austin, James F. Kemp, Gerald Carland, F. H. Morley, Courtenay De Kalb, C. W. Purington, F. Lynwood Garrison, C. F. Tolman, Jr., Horace V. Winchell.

ARRANGEMENTS have recently been completed whereby Mr. T. A. Rickard, editor of *The Mining Magazine*, will return to San Francisco, within the next few months, as editor of the *Press*, and Mr. H. Foster Bain will go to London as editor of *The Mining Magazine*.

NEW tax regulations covering mining properties in the Philippine Islands have been proposed by the Collector of Internal Revenue, but open meetings are to be held in which mining men and others interested can express their views before enacting the law.

CHINA'S method of creating a merchant marine is to guarantee dividends on the stock of a shipping corporation, in return for advantageous freight rates on certain articles. The shipping corporation, recently organized, proposes to operate ships between China and New York through the Panama canal.

GOLD OUTPUT of the Rand for 1914 was 8,378,139 ounces, as compared with 8,798,336 ounces in 1913, which output is generally considered satisfactory. It is gratifying to note that the war has not affected gold mining operations in the Transvaal, and it is anticipated that the new producers will keep up a steady output. Dividends for 1914 totaled £8,371,228, as compared with £8,596,532 for the preceding year.

CHEMICAL and drug imports which were seriously interrupted during the first three months following the outbreak of the European conflict, have again resumed normal proportions. The November imports were valued at $7,904,944, as against $6,746,147 for the same period of the preceding year. The importation of sodium cyanide, which in August dropped to 84,000 pounds, increased to 2,182,000 pounds in November, greatly ameliorating the American supply.

NITRATE operators in Chile are in a parlous condition. The Chilean government has advanced about $1,500,000 to operators so that they may not have to close down their plants, but this has been of no avail to the smaller organizations, and it is said that many of the small towns are almost depopulated, over half of the plants having already been closed. The exodus has one compensation in that the supplies of food available, which would otherwise have soon been exhausted, will probably suffice for several months.

MERCHANTS all over the world are turning their attention toward the United States, as the war in Europe has served to cut off their former source of supply. The Department of Commerce at Washington is in daily receipt of numerous inquiries for products of every imaginable variety, and the daily *Commerce Reports* has had to largely increase the space devoted to the publication of these inquiries. Copper wire and cable for Europe, tin plate and aluminum sheets for Denmark, mining supplies for the Far East, electric equipment for South America, white lead for Russia, sheet brass for Great Britain, chemicals for Greece, lamp chimneys for miners' lamps in England, mining machinery for South Africa, bichromate of potash for France, locomotive tubes for northern Europe, calamine for the East Indies, tin plates for South America, nitrate of soda and fireclay for Greece, glass for China, and brass wire for Portugal; these are only a few out of thousands. It seems reasonably certain that if our own producers will make concessions when necessary to form desirable permanent connections, instead of taking advantage of present conditions to reap a temporary advantage, a large increase in our foreign trade may be expected.

ANTIMONY has been rising steadily in price, as the good demand from Europe has enabled speculators in the East to clear out their stocks, which were large. Reports from Japan state that large orders from Europe are being received there, but can not be filled, as the Japanese stocks are small and production not large. Orders are also going direct to China, where the Wha Chang Company, the principal producer, has been selling its regulus to the Chinese Antimony Company, a subsidiary of Cookson's, under a contract providing for payment on the basis of the average metal market report in London. As the London market has been low and the New York market high, the Wha Chang Company objected to this basis of settlement, and refuses to make any more deliveries until its contract with Cookson's expires June 30 next. Sales are being made direct to export houses in China, and recent sales to Russia have been reported. As China exports about 15,000 tons of antimony each year, and can produce much larger amounts, it would seem that the present affords the Chinese producers an excellent opportunity to get control of the world's trade in antimony, and the Wha Chang Company has shown commendable foresight in opening a sales office in New York City.

STANDARD OIL operations in China have been made in the public eye, without much in the way of definite result to record as yet. The *Sinwan Pao*, of Peking, has recently stated that the first well in the Yenchang district of Shensi has struck oil at 400 ft. and is yielding 1700 to 1800 *Ko* of oil per day. The translator supposes *Ko* to here mean the Japanese *Koku*, equivalent to $1\frac{1}{8}$ barrels, but it is much more likely to signify a Chinese measure equivalent to 0.01 gallon, corresponding to a flow of some 18 gallons per day. So small a flow from so slight a depth is interesting, but not important. Of more importance is the report that the government at Peking has recognized the Morgan concession, covering mineral rights in Ssuchuan, as valid and binding. This was a blanket concession given to an English group five years or so ago, covering almost every form of activity which might be likely to be undertaken in the province. Nothing of importance was done under it until the Standard Oil Company obtained its concession, when strenuous efforts were made to establish the validity of the earlier one. The occurrence will awaken a chord of sympathy in the breast of all those who have attempted to develop mining property in an old district. The Chinese government, in its contract with the Standard Oil, took upon itself the burden of settling all such disputes, so the event only bears on the Standard Oil Company in that it removes the possibility of development in an area which seemed of some promise.

PROTECTION OF OILFIELDS

The protection of oilfields against the flooding of the oil-bearing strata by carelessness of a few operators is the subject of a bill which has recently been drawn by the State Mining Bureau and submitted to the public for criticism or suggestion before introduction to the legislature. Mr. R. P. McLaughlin, who has been particularly interested in this movement on behalf of the Bureau, has made an investigation of the existing evils attending the flooding of oil-bearing strata and has proposed a bill which is submitted for the purpose of arousing a discussion of the subject.

The proposed bill provides that the owners of property representing one-half or more of the oil-bearing ground in any community who desire to prevent injury to the oil-bearing strata by the infiltration or intrusion of water, may present to the board of supervisors of that county a petition setting forth their purpose to form an association for the protection of such ground within certain boundaries. These mutual protective organizations will be administered by a board of trustees who shall have power to provide all necessary ways and means for the proper protection of the oil-bearing strata in these districts and shall act as judiciary bodies for deciding all questions relating to the protection of these strata. An engineer is provided to act in an advisory capacity to each board of trustees, whose duty it will be to investigate and make recommendations to the trustees as to the experimental and repair work necessary. The trustees are empowered to order such repair work as is necessary upon wells which are adjudged a nuisance, and if such work is not completed within a certified time, it will be ordered by the trustees and the costs for such work will constitute a lien against the property. This bill is a modification of the old Sutherland bill, which provides for the formation of districts entirely under local management.

The discussion of the McLaughlin bill has resulted in the framing of a second bill which provides for state supervision of the work contemplated in the various districts. This second act for establishing and creating a department of the State Mining Bureau for the protection of the natural resources of petroleum and gas from waste and destruction through improper operations in production is drafted for the same purpose as the first bill, but differs in the method of execution. Under this second bill, a separate department of the State Mining Bureau is established which shall be under the general jurisdiction of the state mineralogist, who shall appoint an oil and gas supervisor whose term of office shall be four years. Both bills are about to be introduced in the Legislature and will be published and distributed by the State Mining Bureau. As the bills can not be voted upon before March, there is time for a further discussion, and it is hoped that a more general expression of opinion may be obtained. The subject has come to be one of primary import in certain of our oilfields, and as such the present action is timely, and a serious consideration is well worth while.

PROBLEMS OF LABOR

The daily papers in New York last week recorded that the Industrial Workers of the World had begun to organize a rent strike among the unemployed, on the theory that a man who is receiving no wages should not be required to pay rent. It is proposed to extend this to a 'workers' moratorium,' the unemployed to pay for nothing until work is forthcoming. With this is coupled a refusal to work for less than standard wages, and a demand that either work or bread be furnished. The tendency among employers is to dismiss such demands as preposterous, and they are preposterous to one who believes that the present system of organization of industry must remain essentially unchanged. The same daily papers which recorded the views stated above also set forth the testimony of Mr. S. R. Guggenheim before the Federal Commission on Industrial Relations. The numerous companies under Mr. Guggenheim's control employ thousands of men, and his views on labor problems are therefore of unusual interest. Mr. Guggenheim was interrogated by Mr. Frank P. Walsh, chairman of the Commission, a prominent lawyer of Kansas. Mr. Walsh had inquired what Mr. Guggenheim's companies had done to help their employees. We give below the more interesting parts of the dialogue as reported in the New York *Tribune*:

"Up to a year and a half ago, when anything unusual arose," Mr. Guggenheim replied, "we immediately did what we could to remedy conditions and make improvements. I told the members of the executive committee and board of directors that we should do more than we had done—we should see to housing the men better, relieve the conditions under which they worked, establish a pension fund—try to throw a helpful, encouraging light into their lives. It meant better business—a higher efficiency.

"We wanted a man who could take full charge of just this—a man who understood what was needed and how to go about to see that what was needed was provided. So we engaged Mr. C. P. Neill, former Labor Commissioner, and told him just what we wanted him to do. We wanted suggestions from him for the encouragement of the men. He went into it, and he has given us lots of suggestions. Some of them are now before our executive committee, and the committee usually follows his suggestions. We have adopted every compensation law that has gone on the statute books."

"Have you or your companies ever opposed legislation benefiting the workingman?"

"Never," Mr. Guggenheim replied. "We adopted every compensation act as soon as it was passed. We are now trying, in our Perth Amboy plant, the experiment of insuring our workers, single or married, so that from $500 to $1000 is paid in the event of death.

"I am a member of the labor committee of the American Smelting and Refining Company. When we hear that conditions are bad in this or that plant, the matter is brought to the attention of the executive committee and an investigation ordered, and then, if conditions are found to be bad, the situation is at once changed. I would have nothing to do with a company that refused to do that."

"Do you oppose the policy of organized labor?"

"Employees are fully justified in organizing. Very often the capitalist is very arbitrary—just as the laborer is, at times. I have no objection to what our employees do outside the plant. They are human."

"Do you think industrial discontent is increasing?"

"I think it is on the increase and will continue to increase unless something is done to prevent it. The high cost of living is partly responsible for that, but the greatest canker known to the world is envy. A man these days sees so many things to invite his envy. But envy is a pretty well distributed trait.

"I think we are getting to a higher standard in dealing with labor, just as I think the world today believes it no longer necessary to kill off your competitor to get along or grind down your fellow man.

"There is not enough legislation. I am not one of those who complain that our statute books are cluttered up with useless laws for changing this and that. We are many years behind England and Germany in legislation which helps the workingman—the poor man.

"There is today too great a difference between the rich man and the poor man. To remedy this is too big a job for the state or the employer to tackle single handed. There should be a combination in this work. The men want more comforts—more of the luxuries of life. They are entitled to them. I say this not because I have enough and always have had, but because humanity owes it to them."

"Do you think the workingman should have a voice in the arrangement of the conditions under which he labors?"

"The workingman should have not only a voice—he should have a compelling voice. And he is getting it. The workmen's compensation act was won by the workingman. He will win more legislative victories. And legislation that will benefit the many is desirable, no matter what that legislation is."

"Have you a remedy for relieving this unemployed situation?"

"I think the state should furnish work for the men who lack employment. You may call me socialistic, if you like, but it is a job of the United States to look after its people. Were it not for philanthropic work there would be a revolution here.

"But enough is not given in this cause. People won't give up money they make. They hold it too dear to them. They won't give it up, even though they have more than they need. They reason that they haven't too much. So the government must raise the money—raise it by taxing the estates of the rich, if you will—but the United States must raise it some way.

"An evil of philanthropy lies in the fact that its proposed beneficiaries feel themselves placed in the light of paupers. Thousands of persons are too proud to accept help unless they can give something in return. Many of them prefer to starve. They want help—money—but they want to work for it.

"In the scheme of uplift in which we are all interested, I think, I believe the workers are entitled to share in the profits in all industries. This should be so arranged that the money could be taken in bulk at the end of the year and deposited to their account in a banking institution. If that were done it would change conditions in thousands and thousands of homes.

"Workers, in the mass, do not understand how to save. My method would teach them. It would be the same as teaching a child to read and write. The people in this country, who have built up fortunes in the last ten or fifteen years, have done it because they have been thrifty. Many are poor because they did not save. Sometimes, of course, fortune comes without thrift, as in the case of the son of a worthy or unworthy sire. The sons of the rich, in many cases, are entitled to great sympathy, though I would not say as much sympathy as the poor."

Mr. Guggenheim closed his testimony by stating that pension systems increase the efficiency of the men, and that his companies are run on the open-shop policy. We have often expressed our own views on labor problems, and, considerations of space forbidding, will not pursue the subject further here.

PIT RIVER AND WORKS OF NOBLE ELECTRIC STEEL COMPANY.

The Manganese Industry in California

By SAMUEL H. DOLBEAR

California has been a producer of manganese ore for nearly fifty years. During this time, there have been lean years in which no production was recorded; of the early output a considerable percentage was consumed by chlorination plants. Since the cyanide and other processes have practically destroyed this outlet, most of the ore mined in recent years has been used by local steel mills and dry cell manufacturers. Considering the fact that this industry has had a long period in which to develop, and that its entire production to date is only about 13,000 tons, it has not enjoyed the prosperity to which it is entitled.

Manganese ore is known to occur in thirty-three counties in California, and there is no doubt that some of these deposits are large enough to justify further exploration. Distance from transportation and high freight rates to consuming centres will, of course, exclude some of these deposits from consideration, but there are several close to rail, and two or three within fairly low freight rates to tidewater.

While India produces large quantities of this ore, the Caucasian deposits of Russia are undoubtedly the most important. Much of the crude ore shipped ranges from 75 to 80% MnO_2, and that ore which has been prepared by washing, amounting to about 15% of the total production, carries from 80 to 90% MnO_2. The deposits of India, however, supply over one-half of the ore consumed in the United States, the imports from that source being several times greater than those from Russia.

The principal use for manganese ore is in the manufacture of the iron-manganese alloys—ferro-manganese and spiegeleisen, with lesser amounts in the silico-manganese alloys and some others. As Germany is the largest producer of these alloys, every nation playing any important part in the manganese industry became involved in hostilities last August, with the exception of Brazil, with an annual output of crude ore of but 60,000 tons, and the United States. The United States is a factor of importance only so far as the manufacture of manganese alloys is concerned. Manganiferous ores of Colorado and Arkansas have been used in the past for the manufacture of ferro-manganese and spiegeleisen, but their principal use is in the fluxing of ores. Similar ores from the Lake Superior section, as well as those of Arkansas, are said to be used in the production of high-manganese pig iron. The only important source of manganese for the manufacture of its alloys in this country is in its occurrence as an impurity in the zinc ores of New Jersey. The greatest output from this source was in 1910, which, according to figures of the United States Geological Survey, amounted to 141,264 long tons. The average yearly output will probably not exceed 110,000 tons. The production of manganese ores is small, averaging about 4000 tons per year, and during several years recently it fell far below this mark. Virginia has shipped the largest amounts—the mines of this state having yielded about 250,000 tons.

Manganese Alloys

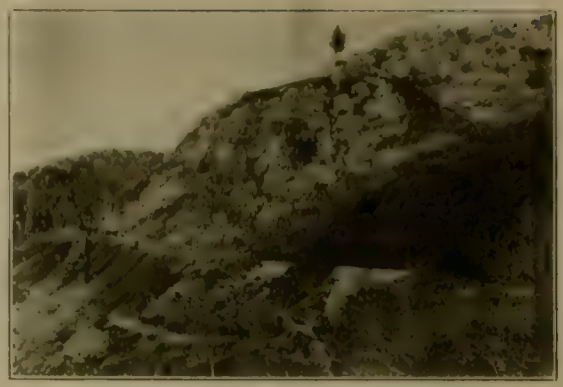
The United States depends upon European countries for about 35% of its manganese alloys. As it has appeared likely that the steel manufacturers would have to operate at a low percentage of capacity on account of the general industrial depression, the situation would not appear at first glance to be especially alarming. But a large part of our average yearly production of about 230,000 tons is manufactured by the larger steel mills for their own use, and this fact accounts for the unprecedented rise in price in this commodity. Prices as high as $140 per ton are said to have been asked at one time. The present quotations are from $60 to $70 per ton at Baltimore, with little demand.

An authority on the subject, formerly engaged in the manufacture of alloys at Niagara Falls, has recently predicted that if the war in Europe should continue for one year, ferro-manganese will command an active market at $100 per ton. That California may become a producer of these alloys is not at all impossible. Attempts in this direction have already been made by two concerns, and the field is being carefully investigated at the present time by two others. A good deal of doubt has been entertained by some as to the possibility of producing a product cheap enough to compete with eastern and European manufacturers. That cheap power may be developed on the Pacific coast is generally conceded. The high cost of labor and the problem of bringing cheap power and the crude constituents together is the factor yet to be determined. What I have already said in my discussion of magnesite and the labor problem in a previous issue of this journal, will aptly apply to this case. An influx of European labor to the Pacific coast through the Panama canal will doubtless follow in time, and as the law of demand and supply pertains to labor as well as to other things, it must result in a revision of our wage schedules. How long this change will be deferred by the European war is theme for prophets. It is possible that the high prices which are likely to prevail in the interim will permit our manufacturing at our present labor rates.

Other Uses

Aside from its use in the preparation of manganese alloys, as above stated, less important amounts are demanded in the various arts. In two industries, which formerly consumed variable amounts, its use is now practically obsolete. The chlorination process has been supplanted by other methods, and there is little call for it now in the manufacture of varnish. The trade now demands transparent or light colored varnishes, and cobalt compounds, in spite of their cost, are used. A large amount of high-grade ore is used in the manufacture of Leclanche and dry cells. For this purpose, as in its application in the glass industry, the demands are very exacting, and the ore must be crushed to the proper fineness and must contain only negligible amounts of impurities, particularly iron. Its principal function in glass is to prevent the green color so common in the cheaper grades. It also imparts the purple and dark brown or black colors, depending upon the quantity used and its method of application. In the ceramic arts, it produces dark colored products and is often crushed to such size as will pass a No. 15 screen and be retained on a No. 60 screen, and in this form used sparingly to produce a mottled effect. Ground to nearly 200 mesh, it forms the color basis of some paints. In the manufacture of chlorine, bromine, oxygen, potassium permanganate, and other salts, there is some demand. Manganese salts finding various applications in the arts and in medicine.

ELECTRIC SMELTER, HEROULT, CALIFORNIA.



MANGANESE MINE AND QUARRY.

Prices

Crude ore from the Tesla mines has brought prices ranging from $8 to $18 per ton during recent years, according to the amount purchased, and purpose for which it was to be used. Where it was sold for dry battery manufacture, and consequently required careful selection, the ore was sold for $14 to $16 per ton at the point of shipment. Some of this ore was ground roughly in burstones before shipment. For use in the steel mills, the crude ore is shipped without any preparation, and sells for about $10 per ton at the point of shipment. This price applies, of course, for occasional carloads. Recent contracts for large amounts are understood to have been made at about $8 per ton on cars. A figure such as this should allow a substantial margin of profit from the Tesla mines. The actual cost of mining and transportation to railroad will depend largely upon the amount of ore handled. At the Winship-Doak mine, there is an opportunity for low cost of operation, if the mine be equipped and handled properly.

Western Manganese Company

This Company, of which Sumner Merrick is manager, has recently entered the California manganese field. The Company purposes to refine manganese ores and has nearly completed a plant at Alameda for this purpose. As a result of extended experiments with California ores, a plant has been designed which seemed best adapted to these ores. The plant comprises in a collective sense,

two parts—a mechanical unit and a process for chemical treatment. The mechanical treatment consists of crushing, sizing by screens, washing, and jigging. At this point, the product receives chemical treatment, the nature of which the Company, for reasons of its own, declines to divulge. The principal impurities to be removed are classed as 'insolubles,' of which silica is the greatest, with lesser amounts of alumina and magnesia. According to Mr. Merrick, ore containing 55% MnO_2 when refined by this process, resulted in a finished product, carrying 91.75% MnO_2, less than 1% Fe_2O_3, and a phosphorus content below 0.001%. All soluble impurities are treated in the chemical unit. The finished product is intended for use in the dry cell, glass, ceramic, and other trades. A contract for minimum ore shipments of two hundred tons per month has been made with the Winship-Doak mine, the plant having an estimated capacity of twenty tons per day of refined manganese.

Noble Electric Steel Company

At the plant of the Noble Electric Steel Co., exhaustive experiments have been made in the production of pig iron in the electric furnace. Its equipment, therefore, required but little change to permit the manufacture of ferro-manganese. When the price of this alloy soared to $100 per ton and above, such figures represented a very satisfactory margin of profit. Many authorities believed that these high prices would continue to prevail so long as war continued in Europe. It was the assurance of these authorities that such was the case, that led the Company to purchase six carloads of manganese ore from the Corral Hollow deposits. According to John Crawford, Jr., the superintendent, this ore was both too impure and too expensive, and would not pay to use at the present prices of manganese alloys. After investigation of a number of local manganese deposits, a lease was taken on the Thomas mine near Ukiah in Mendocino county. The ore here is said to be high grade, and is but four and one-half miles from Redwood station on the Northwestern Pacific railroad. As the roads here can be used only during the dry season, no shipments of ore will be made and consequently the plant will not be operated before March 1915. The furnaces have a capacity of twenty-five tons of ferro-manganese per day, and will be worked to capacity, provided the price prevailing at that time is high enough to insure profitable operation.

The most important occurrence of manganese noted in California is in the Tesla district about 12 miles southeast of Livermore in Alameda county. Most of this ore produced in the state has been mined in this section. The largest individual producer was probably the Ladd mine, controlled by the Caire estate. Most of the ore was sold to chlorination plants, and when this market ceased, about 1902, the mine was sold and has since been only an occasional producer. Three shipments are said to have been made to England from this mine, but this statement, so far as I know, remains unconfirmed.

Winship-Doak Mine

This property adjoins the Ladd mine, and the deposits, which were largely worked out to a depth of possibly 400 ft. in the latter, extend into the ground covered by the Winship-Doak lease, and may be traced for over half a mile by surface croppings and small adits and trenches.[1] The occurrence of this ore has been described by Harder as in a fault fissure; owing to considerable irregularity in the size of the vein, which averages perhaps five or six feet, it has often been referred to as a series of lenticular masses of ore. The strike may be followed for considerable distance and the ore shows continuity throughout the present exposures. The ore is largely psilomelane associated with manganite and pyrolusite.

The promise of the existence of a deposit equal to the Ladd mine seems good, although but little work has been done on the Doak property. The main workings of the old mine extend to the boundary of the Doak lease and should indicate pretty clearly the ore possibilities in the undeveloped area covered by the lease. The old workings extended to the surface from the tunnel at the bottom of the hill and were said to have furnished a back of about 400 ft. This seems rather deeper than the contour of the hill would indicate, and at the time of my visit in the summer of 1912, the old chambers were badly caved and for the most part, inaccessible.

The Winship-Doak lease has been operated intermittently by W. C. Doak for several years, some of the ore being used in the manufacture of dry cells, but more recently has been shipped principally to a local steel plant. Six or eight carloads have been shipped from this mine during the latter part of 1914, a portion of which was used in an attempt to produce ferro-manganese. Owing to the lack of care in the selection of this ore, it is said to have carried too great a percentage of silica and was not suitable for the purpose. The remaining amount was purchased for steel use. The mine is very fortunately situated from a point of transportation. It is but two and one-half miles to Carnegie, a station on the Western Pacific railroad, and enjoys a low freight rate to San Francisco.

Thomas Mine

Attention has recently been drawn to this property through its having been leased to the Noble Electric Steel Co. The mine is in Mendocino county, about nine and one-half miles from Ukiah. The nearest railway is Redwood station on the Northwestern Pacific railroad, a distance of about four and one-half miles. The mine consists of nine claims and ore is said to occur in all of these. These claims are arranged end to end along the strike. The five most northerly claims are looked upon as the most valuable.

According to John Crawford, Jr., no work has been done to determine the extent of the deposit, and it is not apparent from present exposures whether the ore is continuous or is a series of lenses. The croppings, however,

[1] *Bull.* 427, U. S. Geol. Survey.

WESTERN MANGANESE CO., ALAMEDA, CALIFORNIA.

are bold, and in one place extend twenty-five feet above the surrounding surface. Large boulders of good ore are also found on these claims, which, taken with the prominent outcrops, are a sufficient indication of the extent of the orebody to justify the construction of necessary roads and further exploration of the claims.

Analyses made at the direction of Mr. Crawford show percentages of manganese dioxide, ranging from 61 to 84 in much of the ore. The samples analyzed were intended to represent the average ore for the full width of the exposures, and the lessees anticipate no trouble in securing shipments of ore averaging about 80% MnO_2 or about 50% metallic manganese.

Except for its remoteness from the railroad, the mines of the California Manganese Co. are said to be quite promising. The claims are situated near the Stanislaus and Santa Clara county boundary lines and about forty miles from Patterson on the Southern Pacific railroad, and about an equal distance southeast of Livermore. The manganese-bearing belt may be traced for over a mile, the ore occurring in irregular lenses and veins. On the southern portion of the property is the most important occurrence of ore, which can be traced for several hundred feet in length and has been exposed for a width of from five to ten feet in the tunnels. Much ore is said to contain as high as 75% or more Mn_2O_3.

Miscellaneous Deposits

Space will not permit the mention of the many deposits found in nearly all parts of California. There are numerous abandoned workings in the Livermore-Tesla district, and other deposits which have been but slightly prospected. One of these latter is the Mammoth mine, belonging to W. C. Doak, about ten miles south of Livermore.

Very pure ore, specimens of which are said to run as high as 90% MnO_2, is reported on the Newport ranch near Winchester, Riverside county. Manganese ore has been mined within the past year or two at Kleinfelter, a station on the Santa Fe railroad about fifteen miles west of Needles, in San Bernardino county. The ore, here, carried a baryte gangue, with which it was intimately mixed. Two or three hundred tons had been piled up for shipment at the time of my visit. According to the owner, the ore was to be finely ground for use as a pigment, and the presence of baryte was considered desirable, as it gave weight and body to the paint.

Manganese ore is found on the United States military reservation at the Presidio of San Francisco, and on Red Rock island in the San Francisco bay. It is found near Sausalito in Marin county. In Calaveras, Tuolumne, Plumas, Fresno, and San Luis Obispo counties, manganese ore is found in quantities which may warrant further exploration.

Coal-Dust Fired Reverberatory Furnaces

Reverberatory furnace No. 8, of the Washoe smelter, Montana, which is using pulverized coal as fuel, marks quite an advance in reverberatory smelting, according to L. V. Bender in *The Anode* for January. This method of firing furnaces does away with grating, the ash of the coal being either absorbed by the molten mass or drawn by the gases into the flue which connects the furnace with the Stirling boilers. This is a decided advantage to the skimmers and helpers on that furnace. The cleaning of the grates is hot disagreeable work, and no doubt the workmen are glad to be rid of it.

To prepare coal for this method of firing, it is first crushed to one-inch maximum size. It is then dried in a long, rotating, cylindrical-shaped dryer until it contains 1% or less of moisture. This drying makes it easier to pulverize as well as increases its efficiency when it finally reaches the furnace. After drying, it is pulverized in a mill which does its work something similar to a Huntington mill. This mill reduces the coal to a fine powder. The separation of the fine particles from the coarse is not done by a screen, but by means of a current of air, the fineness depending upon the pressure of the air. Whenever a particle is too large to be carried away by the current of air, it falls back upon the grinding surfaces for further pulverization. From the cone-shaped dust collector the dust is conveyed to a bin above the furnace. It is then fed by a screw, dropped upon a nozzle through which air is forced by a fan, carried into the furnace, and instantaneously ignited. All machinery and conveying apparatus are carefully covered to prevent the powdered coal from escaping. This furnace smelts double the tonnage of either of the grate-fired furnaces.

Transactions on the New York Stock Exchange during the week ended December 19, 1914, totaled 960,910 shares and bonds worth $9,476,000, compared with 1,588,056 and $11,887,000 in that week of 1913. The Exchange was only reopened during the previous week after being closed for 4½ months.

Copper concentrate produced by the Elmore process at the Sulitjelma mine, Norway, in December, amounted to 1162 tons.

The Influence of Slag and Fumes on the Zinc Muffle

By O. PROSKE

*Various experiments have been made to determine the effect of slag and fumes as they occur in the zinc muffle. It was first necessary to establish the absorption of ZnO by clay and the combination of ZnO with the individual constituents of the clay. The investigations followed three lines of attack, on the theory that the three following factors were the most important.

The diffusion of gases is increased (1) with the pressure, (2) with temperature, and (3) with time. It is impossible to embody all three factors in any one test.

The idea of using a small retort had to be discarded, as a furnace was not available that would stand the high temperature. A daily heating of the muffle would be injurious to such a sensitive material and might cause erroneous results through cracking. The three factors were therefore investigated separately.

Apparatus

It is almost impossible to construct a suitable apparatus to determine the degree of diffusion of zinc fumes because of pressure and also the absorption of zinc by the clay. The idea of using the gaseous pressure of the zinc fumes at high temperatures was employed in the following way. A clay sphere containing about 5 gm. of ZnO mixed with other ingredients was made as follows: A sphere of 6 cm. diameter was made with a pocket in the centre and an opening leading thereto. This centre was filled with the mixture and a clay stopper inserted into the hole and molded coherent with the rest of the clay. This thickness of clay was deemed necessary to prevent bursting and cracking. The drying took about two months, and the burning was accomplished by gradually increasing the heat. The result was a hard solid sphere, the surface of which showed cracks in only rare instances.

The Hallescher clay used was dry crushed to a slime and had the following composition: SiO_2, 61.44%; Al_2O_3, 26.76%; Fe_2O_3, 1.04%; CaO, 0.49%; MgO, 0.10%; moisture, 9.63%; alkalies, 0.51%. This clay was selected because it is well suited and burns hard and solid. Twelve balls were made in this manner, eight of which had no reducing agents, and four had the addition of a nucleus of burned clay in order to reduce the density and thus increase the diffusion. The compositions were as follows:

1 and	2—5 gm. c.p. ZnO	
3 "	4—5 gm. commercial ZnO	
5 "	6—1 gm. sugar coal, 4 gm. ZnO	
7 "	8—3 gm. ZnO, 4 gm. PbO	
9 "	10—5 gm. commercial ZnO	Mixed with burnt clay
11 "	12—4 gm. ZnO, 1 gm. sugar coal	Mixed with burnt clay

There are here two sets of experiments to avoid accidents. The balls were heated gradually in a gas muffle to 1400°C. At 1000°C. one of the balls exploded with a loud report. This was ball No. 6, which through the reduction of ZnO and the resulting formation and expansion of CO, caused the explosion. Ball No. 5 soon followed with a pronounced crack. At 1200°C., No. 11 and 12 showed fissuring with a Zn colored flame. At 1100°C., No. 8 showed fissuring and the formation of a hole in the vicinity of the burned-clay nucleus. Apparently the Pb silicate must have been quite fluid to have eaten its way through the shell. Ball No. 7 developed a crack on cooling which penetrated the spot where the PbO had made the greatest inroads into the shell.

In comparing tests 1 to 4 with 11 and 12 it is noted that No. 3 developed a slight crack in burning which at 1400°C. became pronounced, and therefore must be eliminated. In breaking open 1 to 4, there was more ZnO left than in 11 and 12. It was impossible to weigh the residue because the ZnO, partly yellow in color, was irretrievably sintered into the clay. In 11 and 12 it was plainly seen that the material was less dense than in No. 1 to 4. Volatilization would naturally increase with decrease of pressure, and the greater the fumes the greater the pressure.

On breaking the clay balls, which required heavy blows of the hammer, it appeared that at the parting wall or contact the color was a clean white which in approaching the centre became pale blue, and in the vicinity of the ZnO became darker blue. No difference could be noted in the effects of chemically pure and commercial zinc. In balls No. 11 and 12 the blue color could be seen at different points. One of these patches was pulverized and treated with concentrated HCl. The Zn silicate goes into solution, while the Zn aluminate remains insoluble. The solution gave ZnO, 0.12%; the total ZnO of the pulp was 4.40%, indicating that almost all of the Zn was combined with Al_2O_3 of the clay material.

Microscopic Examination

A microscopic examination was not made. ZnO has a strong affinity for Al_2O_3 and SiO_2 at these high temperatures even without a reducing atmosphere. If the theory is approved that the thick walls retain the Zn, it is known that if the ZnO of the mass remains constant the clay has absorbed it. The entire ball was pulverized and on analysis showed a content of 4.80 gm. of ZnO for the entire ball, so that it is safe to assume that none escaped.

This method of putting substances in a clay ball to determine effects will be tried on the slag-forming metals such as Fe and Mn with different percentages of S. In this way the reducing action of the fuel gases is avoided.

*Translated from *Metall und Erz*, XI, N. F. II, by F. Sommer Schmidt.

It is necessary to use great care in making the balls, and it requires a long time to dry and burn the clay.

Manifestly the clay has great capacity for absorbing ZnO, and it is the Al_2O_3 constituent that does it. In general, it can be said that the more acid the retort the less loss of Zn by absorption, and the more basic the greater the loss. It must be remembered that there are other factors, such as the tendency to form cracks, which give the ZnO greater surface for attack.

Relation of Time to the Absorption of ZnO by Clay

The greatest absorption takes place in the first day. This is conditional on the muffle being burned solid and that the fusion does not protect the clay. In order to determine what part the element of time plays, the following experiments were performed. A graphite crucible, 9½ cm. high and 5½ cm. upper diameter and 2½ cm. lower diameter, was prepared. Zinc oxide mixed with other compounds was introduced and heated in a muffle to 1300°C. A circular clay disc or plate was embedded in the mixture at about 8 cm. under the upper rim of the crucible. The plates had a diameter of 3 cm. and a thickness of 1½ cm., and were made of the clay described in the preceding experiments. These plates were dried for six weeks and heated to 1000°C. for 10 hours. The idea in these experiments was to determine by increase in weight the amount of absorption of ZnO. This could not be done satisfactorily, as in some cases the attached ZnO carried some of the clay with it when separated from the plate.

The temperature was held at 1330°C. for 8 hours per day for a period of 12 days. In this way only a small portion of the contents could have an effect on the plate, as this remained free in the mass and the greater part of the fumes naturally followed the line of least resistance alongside the clay plate.

The increased time of trial gives some data on the absorption. On the first day a blue coloration was noticeable on the surface of the plate. On breaking the plate it appeared that in certain places the color had already penetrated somewhat deeper, but only on cracks which were often too minute for the naked eye.

On the second and third days one could detect a deeper color, but the rate of absorption decreased daily. The color was always unevenly distributed and mostly along cracks in the plate. Here again it is seen that in the case of a dense material devoid of cracks the ZnO would make much less progress.

The absorption varied greatly in individual cases. After six days one plate contained 2.34% ZnO, and a second 6.78%. These results do not apply to the whole plate, but only the 3 mm. next the surface.

There were 10 crucibles with different mixtures, each one having a burned-clay plate. Crucible No. 3 alone had an air-dried plate.

Crucible No.	Mixture.
1	ZnO, commercial
2	ZnO, chemically pure
3	Air-dried plate, ZnO
4	ZnO and C, 3 to 1
5	ZnO and PbO, 10 to 1
6	ZnO, PbO, C, 8 to 1 to 4
7	ZnO, ZnS, 10 to 1
8	ZnO, ZnS, C, 8 to 1 to 4
9	ZnO, Fe_2O_3, C, 8 to 1 to 4
10	ZnO, CdO, 50 to 1

In crucibles 5 to 9 it was apparent after the first day that a layer of slag had attached itself. A blue color was visible under this, but not so pronounced as in the other tests. In 7 and 8 the reason for this slag formation is that the ZnS was richer in Fe and SiO_2. The slag rim was more pronounced on the second day. Then the plate could not be extracted. It was stuck fast. On this account it was necessary to break crucibles right along in order to allow fumes to escape that would otherwise have been retained. For this reason, tests following No. 4 were not treated after the fourth day. The slag did not show a marked effect on the clay. It was further advanced in some places than others, due to cracks, and caused a somewhat stronger blue coloration.

At a temperature of 1100°C. almost all crucibles showed bubbles on the outer wall which disappeared on further heating. The bubbles were white, thin walled, and delicate, and were of different sizes up to 1 cm. diameter. It can be imagined that at this temperature the ZnO was partly reduced by the graphite crucible, the metallic Zn fumes being drawn into the muffle, where the oxidizing atmosphere of the muffle caused the formation of ZnO on the outside of the crucible. On mixing this ZnO with the carbon of the crucible, the ZnO was reduced, which could be oxidized again by the atmosphere of the muffle. The diffusion of Zn fumes through the walls of the crucible could have been foreseen, but it would naturally be expected that they would avail themselves of the better escape to the surface.

Twelve-Day Test

The plates 1, 2, 3, 4, and 10 showed no change after 12 daily heatings. In course of time, more ZnO was absorbed, but not in proportion to the time. The first day showed the maximum absorption. The individual plates showed after 12 days the following absorption:

No.	ZnO absorbed.
1	4.43 per cent
2	2.18 " "
3	10.34 " "
4	1.08 " "
5	4.38 " "

It must be remembered that this ZnO content is figured on the whole plate, but that the outside of the plate showed the strongest absorption while the interior often showed only traces. That these results do not compare well is due to other considerations, chiefly structure.

The ZnO in No. 3 is strikingly high. The plate was of unburned clay, causing numerous cracks, giving the

ZnO better access. In plate 4 the greater part of the ZnO was reduced so that only a small portion was available. It will be noted that the temperature of reduction of ZnO is lower than that of volatilization. These tests show that the element of time plays a big part, but that, after all, the structure of the clay, porosity, and cracks, is the more important factor. It can be said that where a gas is penetrating a solid it is largely a question of the amount of surface exposed.

Effect of Temperature on Absorption

In the third series of experiments the absorption was noted under varying temperatures. According to Doeltz and Graumann, ZnO begins to volatilize at 1200°C., but I find ZnO in the clay of the muffle at considerably lower temperatures. This is due to the easy oxidation of the Zn fumes by carbonic acid and other gases of the atmosphere. As the fusing point of Zn is lower than the volatilization point of ZnO, there is an absorption of ZnO at a lower temperature than 1000°C. The furnace, even at this temperature, shows the presence of ZnO.

In some plates which were in ZnO and C for 10 hours at a temperature of 1000°C. the characteristic blue color appeared at the edges. The ZnO was all combined with Al_2O_3 because on treating the powdered clay with HCl only 0.10% ZnO was in solution, while the total ZnO was 1.02%. For the following experiments, the same kind of clay discs and crucibles were used as in the previous experiments.

In order to determine the effects of higher temperature, an electric furnace was used, such as has been described in *Metall und Erz*, 1913, page 511. Because of the large diameter of the crucible, it was necessary to widen the chimney to accommodate the increased air pressure. It was found advantageous to coat the pipe with a mixture of clay and carbon, as this protected the pipe from the oxidizing atmosphere.

In order to insure a good contact, a sheet of copper was put between the iron and the carbon plate. Because of the air pressure of the heating tube, it was necessary to have about 1300 amperes with seven volts, in order to attain 1800°C. Two cables designed to carry 1250 amperes were used because they could be depended upon to carry 1500 to 1600 amperes at a temperature of 1800°C. The temperature could not be measured over 1300°C. with a Le Chatelier pyrometer. The guard pipe was porous to gases at this temperature. The Zn fumes caused a disturbance in the wires at a temperature over 1300°C., but they had very little effect on the pyrometer wires. The temperatures were measured up to 2000°C. with a Wanner pyrometer.

No exact gradations of temperature could be determined because the burned CO mixed with metallic Zn fumes gave a colored flame at the mouth of the pipe. They could be determined, however, in a manner satisfactory for the purpose. The carbon-flue oven proved unpractical for this purpose owing to its inability to retain high temperatures. The time used in these experiments never exceeded 1½ hours. There were, therefore, many imperfect contacts which led to a speedy destruction of the furnace. Several attempts were made to use a gas blast-furnace called a Fletcher furnace. As lower temperatures were used in this case, the time of trial was longer, that is, 6 hours.

The clay plates in the electric carbon-pipe furnace were treated for 1½ hours. The individual temperatures were attained in 1 hour, and the maximum was maintained for ½ hour. The experiments are tabulated in Table 3. Clay plates were then studied at different temperatures in a graphite crucible without any mixture.

At 1650°C. the disc was still unfused; at 1800°C. it was converted into a black-gray mass; at 2000°C. and over, the greater part of the disc was volatilized. On the upper part of the carbon pipe, a sort of velvet layer, consisting of minute needles, was noticed.

To see how muffle furnaces consisting of a higher carbon content behave at these high temperatures, experiments No. 10 and 11 (see table) were performed. One of these muffles is very acid and the other very basic, and the experiments were made in a Tamman furnace simultaneously. The fusing took place much slower. A large part of the carbon burned out first, then the mass became viscous. Big bubbles, occasioned by the burning coke, had formed, and finally at the end of the experiment it was seen that the crucible was filled with a bubbling molten mass. In the centre of this mass, there appeared, after breaking a crucible, a piece of the muffle not yet molten, which still had its original appearance. As this was entirely covered with the molten matter, the carbon could not burn. This had hardened the fragment to such an extent that it could not be fused at 1900° Centigrade.

Influence of Zinc Oxide

After having observed the behavior of the discs under different temperatures to 2000°C. and over, I think the influence of the ZnO on the discs can be determined from experiments No. 11 to 16. In experiment No. 11, at 1420°C., in 1½ hours, there was noticeable a great absorption, and a particularly dark blue spot gave 8.9% ZnO. In experiment 12, at 1580°C., there was a pronounced and rapid absorption of ZnO.

It is interesting to note the ZnO contents of the plates at temperatures higher than the fusing point of the clay plates. Here is a much quicker volatilization of the ZnO, but less influence of the fumes. One can assume that the ZnO was volatilized before the high temperatures were reached. The carbon flues were closed at both ends, so that there was a strong atmosphere of ZnO. Every plate that was fused had the characteristic blue to black coloration in several places. In breaking the crucibles the cake could be removed and the approximate amount of absorbed ZnO could be determined by weight.

Plate No. 13 weighed 19 gm.; the cake originally weighed 27 gm., and therefore the absorption of 8 gm.

equals .80%. The fused mass had a volume from three to four times that of the original. This is explained by its viscous condition, and that a portion of the ZnO being volatilized, was given to the formation of bubbles. That there was volatilization of ZnO could be recognized by the fact that the upper layer of the cake had a different color from the underlying one. One layer of a ½-cm. was yellow-brown. While there was a marked volatilization of ZnO at 1300° to 1400° C., one sees that in spite of the high temperatures the ZnO is so strongly held that it diminishes very gradually in the upper layers. There is not only a reduction of Zn spinel at high temperatures, but also in the volatilization of ZnO, from the Al_2O_3-ZnO combination. It must be remembered that in the carbon pipe there is a strong CO atmosphere.

The cake on the walls of the crucible had the blue color, and through the uncombined C a reduction of the spinel would take place with difficulty. One sees that the absorption of ZnO by clay and the combination with Al_2O_3 occurs at higher temperatures than the fusing point of clay, up to 2000° Centigrade.

To determine the behavior of a clay plate in a mixture of ZnO and C at higher temperatures, experiment No. 8, containing these ingredients in the proportion of 3 to 1, was performed at a temperature of 1560°C. Experiment No. 9 had the proportion of 2 to 1 at 1600°C. As the coal has an ash which would surround the plate, the coal of sugar was used in excess of the requirements for reducing the ZnO. There was in both cases unconsumed carbon. As expected, all the ZnO in the crucible was reduced before the highest temperature was reached. The plates showed a blue-gray color. The formation of spinel could not be observed. An analysis of the plate showed only traces of Zn. As only metallic Zn fume was formed, no absorption could take place.

In experiment No. 10, there was ZnO and C together with PbO, an average temperature of 1410°C., and a period of 6 hours. The plate showed no fused layer. The PbO was reduced and therefore could exert no influence on the clay. No PbO could be found in the muffle. The PbO is reduced at a lower temperature than that at which volatilization begins, so that the PbO was reduced before it could attack the clay.

The results are different when only ZnO and PbO are used as shown in experiments No. 17 to 22. Only the thinnest layer of slag could be found on the plate which was more developed with a greater percentage of PbO. The greater amount of slag the less the absorption. In these cases only a faint blue color was seen.

In experiments 17 and 18 a slight slag formed and a stronger ZnO absorption took place at the edges, namely, 2.3%. In cooling, the slag cracks in the clay and thus gives a better access to the Zn fumes, and thus by oxidation a greater amount of Zn spinel is formed.

TABLE SHOWING RESULTS OF EXPERIMENTS TO DETERMINE THE ABSORPTION OF ZnO BY CLAY WITH VARYING TEMPERATURES

No.	Substance in which plate was immersed.	Duration in hours.	Max. temp., deg. C.	Furnace.	Condition of plate.	Remarks on the products.
1	Graphite crux only	1½	1600	Tamman[1]	Not fused	Dark gray outside; white inside; very hard; no cracks.
2	Graphite crux only	1½	1650	Tamman	Not fused	Black coating on under surface of plate.
3	Graphite crux only	1½	1800	Tamman	Fused	Hard, dense; no bubbles; some unfused pieces.
4	Graphite crux only, 4 plates	1½	2000[2]	Tamman	Fused	Nothing left in crux; all 4 plates volatilized; crux much corroded.
5	Graphite crux only, 4 plates	1½	2000[3]	Tamman	Fused	Plates mostly volatilized; crux covered with glaze half way, black color.
6	Graphite crux with acid muffle	1½	1900	Tamman	Fused	Black mass, strong bubbles; in bottom a piece unaltered muffle.
7	Graphite crux with basic muffle	1½	1900	Tamman	Fused	Same as No. 6, except less bubbling.
8	ZnO plus C, 3 to 1	1½	1560	Tamman	Not fused	No Zn spinel; outer edge plate black-gray for 2 mm.; inside white. Plate 0.3% ZnO.
9	ZnO plus C, 2 to 1	1½	1600	Tamman	Not fused	Like 8; much unconsumed carbon.
10	ZnO, PbO, C, 5 to 1 to 2	6	1410	Fletcher	Not fused	No slag; some Zn spinel on edge.
11	ZnO	1½	1420	Tamman	Not fused	Strong spinel; interior blue; one sample 8.9% ZnO.
12	ZnO	1½	1580	Tamman	Not fused	Like 11; no stronger blue coloration.
13	ZnO	1½	1830	Tamman	Fused	Mass blue violet; weight of plate 19 gm., with absorbed products 27 gm.; many bubbles.
14	ZnO	1½	1910	Tamman	Fused	Like 13. One spot sampled 30.84% ZnO. Original weight, 20 gm.; weight with absorbed products, 28.4 gm.
15	ZnO	1½	1930	Tamman	Fused	Like the three previous. Original weight, 20 gm.; with products absorbed, 33.4 gm.
16	ZnO	1½	2000[4]	Tamman	Fused	Like 15. Original weight, 19.5 gm.; with absorbed products, 35 gm.
17	ZnO-PbO, 98 to 2	6	1410	Fletcher	Not fused	Blue on edge giving 1.04% ZnO; thin slag.
18	ZnO-PbO, 96 to 4	6	1430	Fletcher	Not fused	Like 17. Thin yellow slag coating. Spinel like 17.
19	ZnO-PbO, 94 to 6	6	1420	Fletcher	Not fused	Like 18. ZnO 0.08%. More slag.
20	ZnO-PbO, 92 to 8	6	1410	Fletcher	Not fused	More slag attacking plate.
21	ZnO-PbO, 90 to 10	6	1440	Fletcher	Not fused	Heavy slag coating. No blue color in plate.
22	ZnO-PbO, 90 to 10	1½	1650	Fletcher	Fused	Transparent green glass, octahedrons of zinc spinel.

[1]Electric. [2]Considerably above. [3]Above. [4]Slightly over.

Iron Mining in Michigan

STAFF CORRESPONDENCE

The total production of iron ore from the mines of the Marquette range for 1914 amounted to 2,463,973 tons. By the first of December all shipments had ceased with the exception of about 2000 tons per week from the Republic mine, which is sending ore by rail to the Algomah furnaces, Ontario; and 900 tons from the Cambria, Negaunee. The tonnage was 1,502,707 less than was forwarded in 1913.

Thirty mines shipped ore during the year. The Cleveland Lake and Cliffs Shaft mines of the Cleveland-Cliffs Iron Co. were the largest producers. The Steel Corporation mines were not very active. At the present time there is a large tonnage of unsold ore at many of the mines. Many are idle, and some are working only part time and with greatly reduced forces. The Cleveland-Cliffs Iron Co. was the largest shipper of ore on the Marquette range, as follows:

Ishpeming group of mines.—Cliffs shaft, 285,310; Chase, 19,708; Lake, 318,204; North Lake, 120,639; Morris, 29,063; and Salisbury, 69,089; a total of 842,013 tons.

Negaunee group.—Maas, 55,903; Negaunee, 247,484; and South Jackson, 20,241; a total of 323,628 tons.

Swanzy group.—Austin, 30,492; Gwinn, 20,151; Princeton, 13,607; and Stephenson, 93,795; a total of 158,045 tons; and the Republic, with 45,316 tons; making a grand total of 1,365,010 tons.

Decreases are shown by all the properties operating during the year. The selling prices* of the ore from the Swanzy group was 75c. per ton under the basis of the valuation as set by the state tax commission.

Shipments from the mines of the Oliver Iron Mining Co. for the year totaled 241,423 tons less than in 1913. No work was done at the Champion mine, Beacon; none at Section 21, south of Ishpeming; and the Ishpeming and Negaunee properties were worked in a quiet way. The Oliver company's shipments were as follows:

Lake Superior group, 86,957; Queen, 178,547; and Stegmiller, 40,972; a total of 306,476 tons.

Breitung interests.—Mary Charlotte, 96,105; Breitung Hematite, 49,055; and Washington Iron Co., 1146; a total of 146,306 tons.

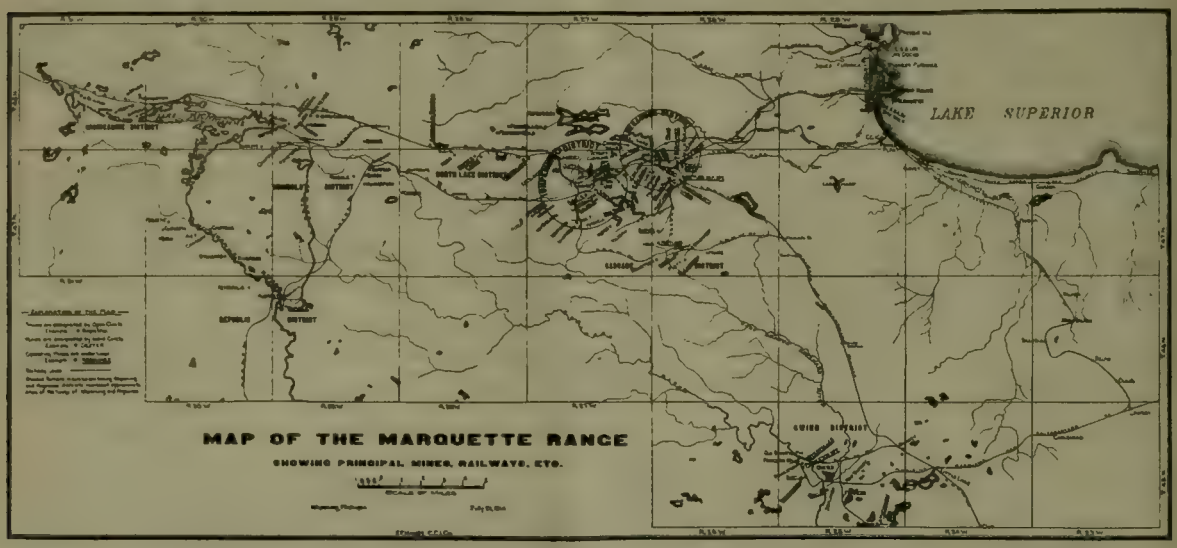
Jones & Laughlin interests.—Pittsburgh & Lake Angeline, 128,073; and Rolling Mill, 98,011; a total of 226,084 tons.

American, 78,887; Portland, 43,323; Republic Iron & Steel, 127,967; Richmond, 129,548; and Volunteer Iron Co., 38,345 tons.

Total shipments from the Gogebic range during the year amounted to 3,363,419 tons. Of the active mines at the beginning of the year, the Asteroid, Castile, Colby, Ironton, Mikado, Windsor, and Yale are now idle.

Total shipments from the Crystal Falls district, with the Hemlock estimated, amount to less than 500,000 tons. It was the poorest year in over a decade. Corrigan, McKinney & Co. shipped 175,000 tons, and the Bristol mine 172,000 tons. The Carpenter and Ravenna mines of the M. A. Hanna company shipped about 100,000 tons, and the Judson 5000 tons.

About one-fifth of the iron ore from the Lake Superior region is now delivered at Lake Michigan ports. For the season just closed these ports received 6,109,019 tons of ore. According to the annual report of the collector of customs of Chicago, receipts of iron ore from the Lake Superior region totaled 5,767,337 tons at Gary, South Chicago, and Indiana harbor. In 1913 the tonnage was 12,530,023.



*Iron Ore.

A GEOLOGICAL SURVEY of the oil deposits of Papua (New Guinea), northeast Australia, shows them to be worthy of commercial development.

Kauri Gum Deposits of New Zealand

By W. D. HORNADAY

Mining kauri gum is an important industry in New Zealand. Enormous quantities of this product are shipped annually to the United States and European countries, where it is used in the manufacture of varnishes and for several other purposes, one of which is to give gloss to linoleum. Since 1853 there has been exported from New Zealand kauri gum to the total value of approximately $85,000,000. The value of the annual production is now about $2,500,000. It is one of the large industries of New Zealand. The total exportation in 1912 was 8014 tons, of which 3964 tons went to the United States and the remainder to Europe. The price paid in Auckland for the gum ranges from $25 per ton for the lowest grade of dark dust to $1800 per ton for the highest grade of bright scraped gum. The average value of the product here is about $375 per ton.

The gum fields, as they are called, cover an area of approximately 914,000 acres of the Auckland province in the North Island. It is considered probable that the producing territory may be greatly extended in the years to come. The valuable product is found wherever the kauri pine forests once existed. Even in wide areas where there is at this time no semblance of a forest having ever covered the barren and often swampy lands, there are found enormous deposits of the fossilized gum beneath the surface.

One of the interesting features of the industry, aside from the large revenue that it produces, is that, of the total area that is now being exploited, the government owns 500,000 acres. Instead of trying to make a direct profit from the gum upon these Dominion lands, the government merely charges each 'digger' a nominal fee of $5 for a perpetual permit which gives the man the right to produce and sell for his own benefit as much of the product as his labor will produce. It is a place where the unemployed may always find profitable work. Many instances are cited where men who are now prominent in the business and industrial affairs of the colony obtained their start in the gum fields. The labor is hard and disagreeable, but the returns are usually good. It is not unusual for an expert in the work to make as much as $40 to $50 per week, and the average weekly return per digger is about $15. At present there are more than 6000 men employed in the different fields. Most of them are Austrians, who seem to find the occupation particularly agreeable. They are said to be law-abiding and industrious, and, inasmuch as the average British laborer finds gum digging distasteful, the Austrians do not come into competition with the organized worker, and are therefore not regarded in an unwelcome light by the masses of unionist employees.

The Gum Industry

The manner in which the kauri gum industry is carried on is only another illustration of the well known fact that many things are done differently in New Zealand from any country in the world. Imagine what a rush of aggregations of capital there would be to exploit a field of this character if it existed in the United States. There is not a corporation or firm operating in the gum district. This is true of not only the Crown lands, but of the privately owned properties as well. The wishes of the government that the fields shall be perpetually held as a sort of workshop for idle or surplus labor is re-

DIGGING KAURI GUM.

spected by private owners of gum-bearing land. The latter lease their properties on a royalty basis. If large dredges were employed instead of the present method of hand digging, the output of gum would be increased enormously. The supply, however, would soon be greater than the demand, and a fall in prices would result. The fields would also be exhausted much more quickly than under the system that is now followed.

The kauri pine, which produces the gum that has brought much wealth to New Zealand, is indigenous to the Auckland province. It is a giant in size, its height often being 120 to 160 ft. The tree varies from 5 to 12 ft. in diameter. The standing forests cover a large area and are the chief sources of lumber supply for the Dominion. Its percentage of resinous properties is high. When scarred by the falling of another tree, the gum oozes from the wound in large quantities. It is so prolific in this respect that a considerable quantity of the product is now obtained by tapping the trees in much the same way that rubber trees are treated. Most of the product, however, is obtained from the ground and is in a fossilized state. It is estimated that the gum which is thus obtained is fully 3000 years old. The trees are of slow growth, a fully matured giant of the forest being from 400 to 500 years old, according to the calculations of scientists.

Digging Operations

The digging process is not without human interest. It has its speculative element, as there is always a doubt as to where the gum will be found and what the day's output will be. Sometimes a digger will find a large pocket of the amber-colored product, and he may realize a return of $50 to $100 from a few hours' work. At other times his labors may go almost unrewarded for a day or two at a time. Scattered all about through the producing region are small stores where the diggers sell their weekly outputs. These storekeepers in turn sell the gum to merchants and commission men in Auckland. The country stores offer every opportunity for a prospective digger to start work. They advance him a week's supplies and provide the necessary tools. The outfit consists of a spade, an ax, and a long sharp-pointed rod, which is used to test the earth near the surface. When a hard substance is prodded, an investigation is made and a lump of gum is usually turned up. The Austrians carry on operations systematically, working in gangs and digging deep and long trenches, prospecting every inch of the ground. The gum is found in two layers or strata, the second one being a few feet below the first. This leads to the theory that two distinct forest ages existed and that the lower bed of gum is much older than the upper one. Large quantities of product of an inferior grade are obtained from swampy lands, which it is often necessary to drain. The lumps of gum vary in size from that of a potato to a half-bushel basket. When taken from the ground the gum is usually encrusted with a white earthy substance. The diggers scrape this off and the chunks present a beautiful appearance. The gum is then sorted according to grade and is bought and weighed in the field. The scraping and classifying are done in the evening, when the day's labor in the field is over. The women and children of the camp or household often help in this work. The gum is re-scraped after it comes into the hands of the merchant in Auckland, and in this manner the grade is improved and a higher price obtained for the product.

BUYING GUM IN THE FIELD.

It is a nomadic life that many of the diggers follow. They wander from one field to another, turning up the earth in search of the valuable gum wherever they may wish. It is thought that the Auckland province will continue to produce the gum in large quantities for many years to come. There are still areas of land that have been little explored. The surface deposits are practically exhausted and the supply of the future must come from underground and from the living kauri trees.

It is desired by the men who are engaged in supplying the American and European markets with the product that there be no large increase made in the annual output, as it would mean an oversupply of the demand and a fall in prices. On the other hand, it is contended by the handlers of the gum abroad that if prices go any higher the manufacturers of varnishes and linoleums will use a substitute and the industry will suffer in consequence. It is the kauri gum that gives the handsome finishing touch to varnish and the increase in the demand is due to the growth of the varnish trade.

The Dominion government is offering encouragement for the settling of the lands which have been mined for the gum. It is claimed that where these lands are properly drained they are well suited for agricultural purposes, particularly for dairying. As an inducement to the Austrians and others to make permanent homes in the kauri country, the government has divided the worked over lands into small tracts which may be homesteaded upon payment of a nominal fee. It was formerly supposed that the gum-producing lands were worthless for crop growing, but tests show, it is claimed, that they produce grass abundantly and that a variety of other products may be grown upon them. The original forests were probably destroyed by fire or by a volcanic disturbance.

Blast-Furnace Practice at Mount Lyell, Tasmania

By ROBERT STICHT

*The Mount Lyell orebodies are wonderful, even though they are thought to be only the 'roots' of a great pyritic mass. They may be assumed to be the lower portion of a once much larger mass, into certain parts of which lower portion the meteoric waters, in times gone by, have concentrated the copper, silver, and possibly the gold contents of the upper portion, which is now gone by erosion. The country is heavily glaciated. In the silicious North Lyell mine, orebodies are found that resemble a bunch of carrots or sweet potatoes, they are so long and chimney-like, and there is reason to think that there was once a more pyritic body above them. The local geologists are careful learned men, but they are eclectic, not original, and have not been able to devote sufficient time to a study of the deposition of this ore.

As regards smelting, when I arrived at Mount Lyell the pyrite method was still a problem. I had enjoyed opportunity to carry it out in its purity, for short periods, whenever the ores were suitable, in Montana and Colorado, and had no fear, on an empirical basis, that it would not be possible to carry it on continuously where the ore was so favorable as at Lyell.

The Mount Lyell company started with three blast-furnaces in 1896, and then installed converters. This plant was gradually enlarged to six blast-furnaces. A second plant was built with five furnaces. When hot blast was abandoned, after six years' use, the first plant was dismantled, and all the work was done in the second. This plant received an extra furnace in the course of time, so that it has six, but usually only three are operated. The most interesting development, perhaps, was the discarding of hot blast. I do not think I would now recommend it under any conditions.

MOUNT LYELL SMELTER AT QUEENSTOWN, TASMANIA.

The furnace column reaches 18 ft. above tuyeres, and 64-oz. blast pressure is used. The work is based on the assumption that the inside of a furnace is occupied by a honeycombed mass of quartz, the passages of which are traversed by the blast and the molten sulphide, in opposite directions, the incandescent silica effecting simultaneous oxidation of the latter, by the oxygen of the blast, and the union of the FeO, thus formed, with the

*Abstract from *Bull.* 79 of Min. & Met. Soc. of America. An address before members at the November meeting.

silica itself. This forms the slag, while the unoxidized portion of the sulphide makes the matte. Our matte runs from 45 to 50%, rarely under 35%, and sometimes as high as 60 to 65% (a 20:1 concentration). When the matte becomes too high, we reduce the silicious ore; when too low, we increase it. The proportion of pyrite in the charge is constant; also the limestone. The only variables are silicious ore and coke, but the latter is changed much less frequently than the former.

Percentage of Coke

As regards the percentage of coke used, I regret to say that the time when only 1.5% (and sometimes as little as 0.1%, with hot blast) was used is now merely historic. It is now necessary to smelt more of the silicious ore, and, at the same time, the iron and sulphur in the pyritic ore have diminished, owing to the inclusion of a little galena and zinc-blende and a little more gangue. As a consequence, from 3.5 to 5% coke is used, figured on the materials charged (except coke). The coke is our own make, but high in ash, and wet from the rainfall, which is 110 in. annually. The slags are also more silicious than they used to be, averaging 35 to 37% SiO_2, against 30 to 32% in the past. The campaigns used to be three months or less; now they are a good deal longer, easily six months, the stoppages being caused by leaky jackets or the forehearth.

Concerning shape of bosh, I am unable to see that it makes any difference. The furnace creates its own internal lines, which may be entirely different from those of the designer. One can alter the position of the smelting zone, that is, the focus, by changing the blast. The focus can be driven up by increased blast; in fact, it may be driven clear to the top of the column.

One might think the works old-fashioned, but they have kept fully in touch with all modern improvements and tendencies in the United States, but it has not been found that advantageous use could be made of the most striking ones. This is true as well of economic as of purely metallurgical points. Each furnace is run individually as regards momentary composition of charge, and the principal factor in their operation is the feeding. One has to be very particular about this, and cannot resort to mechanical appliances intended to serve unchanging average conditions of feed, because the process is so sensitive to variations in the relative proportions of silica, sulphide, and air, and to the physical way in which these three come together. It is not possible to run a number of pyritic furnaces all in the same manner and obtain the present grades of matte with satisfactory constancy. You would have to reduce the grade to, say, 20%, and be satisfied to re-treat this.

In the subsequent discussion by D. H. Browne, J. Parke Channing, and A. H. Rogers, Mr. Sticht argued as follows:

In a blast-furnace you find lumps of silica and lumps of pyrite in contact. In the Knudsen converter you find fused slag and fused matte; hence the blowing occurs under different conditions as to spacial distribution of air, sulphide, and silica, affording different facility for reaction.

Most of the iron in the Mount Lyell ores is burned off, that is to say, 95 to 96%, and in the burning it is also sacrificed and forms the slag. However, I am of the opinion that the materials must be in big lumps to do the work.

Too much stress is often put on the utility of the sulphur in pyrite as a source of heat in this process. That extra atom of sulphur is not burned; it goes off altogether by sublimation, is distilled. The FeS_2 turns practically to pyrrhotite at once, and even to something like Fe_7S_8, or Fe_6S_7, in the lower part of the furnace; and it is this particular sulphide which supplies the heat. In many ways, I think, a pyrrhotite ore is probably easier to smelt pyritically than a pyrite ore, but I may repeat that the most essential condition for the process is to have free SiO_2. What experience I had with pyrrhotite ores in Colorado made me feel that they were easier to treat than pure pyrite. In addition to keeping the throat more free, they seemed to run hotter. But it was necessary not to be afraid to reduce the coke, that is, to a minimum which would ordinarily seem dangerous.

Height of Smelting Column

There ought to be several feet leeway in the height of a smelting column. In reconstructing the Mount Lyell works, I raised the charge floor 8 ft. above the former one. A separate blower for each furnace is desirable if one can afford it, but that is only a minor point when there are not too many furnaces. When formerly using hot blast, the stoves standing between blowers and furnaces, it complicated matters to have a blower for each furnace, and we did not do that at Mount Lyell. The practice now is to supply about 20,000 cu. ft. of cold free air per minute to each furnace. The 64-oz. pressure is only an incidental feature of the blast, and is due merely to the resistance encountered in forcing a given volume of air through a certain size of tuyere in a given time. Roughly speaking, it is volume rather than pressure that counts.

Regarding the composition of the furnace gases, since the figures were first published, I have occasionally repeated the analyses, and still find practically no oxygen in the gases leaving the furnace, nor at a depth of 7.5 ft. below the top of the column. The determinations were last made a few months ago, with a water-cooled apparatus.

The top of the charge looks hot. This is due to the large amount of sulphur distilling off, which burns as it comes in contact with oxygen of the air above the charge. It is possible to run the furnace on matte and pyrrhotite with a satisfactorily cold top. On pyrite, however, this is impracticable, for this low temperature can be achieved only by operating in a manner which leads to rapid formation of crusts around the throat. The furnace is run so as to avoid crusts, and thus appears to have a fiery throat. One must, however,

not contemplate the combustion of the sublimated elemental sulphur, but judge throat conditions rather by the phenomena at the top of column. The top of the furnace is really not hot, for the pieces of charge glow slightly only around the walls, and are black and cold over the full inner area of the top. Between these cold pieces a whitish flame is visible, which changes into a heavy cloud of sulphur vapor, a foot or two above the top of the charge; this then ignites and forms the usual dense white smoke characteristic of the work. The furnace acts as its own crusher; all materials are charged in as massive lumps as the men at the mines and quarries can readily handle. Possibly, if we crushed them first, they would so decrepitate in the furnace that the latter would choke tight, and we could not practice pyritic smelting at all.

Chilean Nitrate Statistics

*The Iquique branch of the Nitrate Propaganda Association reports that the production of nitrate in November 1914 was 2,659,875 quintals (of 101.6 lb.), compared with 4,885,869 quintals in November 1913, and that 54 plants were working in November 1914, against 127 plants in November 1913. The production from January to November in 1913 amounted to 55,193,034 quintals, and in 1914 to 51,071,286 quintals. For the first five months, July to November, of the nitrate year 1914-15, the production was 18,925,310 quintals, compared with 25,100,257 quintals during the corresponding period of 1913-14. In November 1914, 1,910,930 quintals was exported, as against 5,655,841 quintals in November 1913, and the stock on hand November 30, 1914, amounted to 24,168,428 quintals.

El Nacional states that 46 plants will continue to work in December. To November 30, 1914, the loans to nitrate companies by the government amounted to ₱25,836,207, paper, of which ₱3,434,154 had been repaid. The value of the Chilean paper *peso* fluctuated as follows: July, 1914, 20c.; August and September, 18c.; and October and November, 15c. Sales of importance in November were made at $1.45 per quintal. Exports of nitrate from July 1 to November 30, 1914, totaled 11,300,353 quintals, a decrease of 13,000,000 quintals from the exports for the corresponding period of 1913.

THE CONDITION of the copper market in Japan is worse than ever, with no prospects of relief, according to a consular report of December 2. The Mainichi (Osaka) reports the latest quotations for electrolytic copper at 10.65c. per lb., and 98% quality at about 10.50c., but these quotations are only nominal, as there are no buyers.

NEW ROLLING STOCK for railroads in the United States consisted of the following in 1914 and 1913:

	1914.	1913.
Freight cars	104,541	207,684
Passenger cars	3,691	3,296
Locomotives	2,235	5,332

*Report of David J. D. Myers, consul at Iquique, Dec. 15.

Firing Boilers

By ALEXANDER M. ALLEN

*It is well known that boilers working in batteries, though of the same size and style, will not evaporate the same amount of water per hour. In a battery of three 100-hp. boilers, for instance, the centre one will evaporate 3000 lb. (its rated capacity), the one on its right will evaporate only 2000 lb. (1000 lb. below its capacity), while the one on its left may evaporate 4000 lb. (1000 lb. above its rated capacity). Twenty minutes later these conditions may be reversed. This method of getting up steam is not only uneconomical, but unreliable, and may result in injury to the entire battery. Feed water regulators and feed pumps together with raising the temperature of the feed water may help considerably in maintaining a uniform steam pressure and a consequent uniform evaporation, but all of the foregoing auxiliaries are not half so effective as the care and skill to be exercised and practised continually in the fire-room.

Most firemen coal entirely too heavily, and thus permit the fire to lag for one-half hour, sometimes, before it is hot enough to make steam. Evidently time is wasted and the method incorrect. Coal should be burned as rapidly as possible to secure the best results. Since a pound of coal contains a certain number of heat units (B.t.u.), whether it burns for one minute or one hour, it is to advantage to extract this heat and transfer it to the water in the boiler in the shortest possible time in order to get up steam quickly.

To know the necessary amount of air to be admitted into the ashpit of the boiler for the proper combustion of the coal is important, because an oversupply of air may easily chill the furnace. With a grate having an 18% air space and a fire bed of rice coal 8 in. thick, an air pressure of 1.5 in. of water gage was found to be correct. This gage will differ, however, for various styles of grates and kinds of fuel.

A recent experience impresses all the more the importance of correct firing. At a boiler plant the output of which was 150 hp., a fireman was cleaning a rice-coal fire that was about 12 in. thick. First he pushed the good coal back and dropped the front; then he pulled all the good coal ahead and dropped the back, after which he proceeded to spread the partly burned coal equally over the grate. The coal bed was then about 5 in. thick. So far so good. The next move was the turning on of the air-blast and applying fresh coal. The fireman then fed (by count) 140 shovels of coal which at 20 lb. per shovel made a total of 2800 lb. A liberal allowance of coal to make one boiler horse-power is 6 lb. per hour. From this figure it can be seen that the fireman coaled enough to last three hours. Ridiculous, it may be said, yet many men who call themselves firemen have been doing this very same thing all the time.

*Abstract from *Employes' Magazine* of the Lehigh Valley Coal Company.

DISCUSSION

Readers of the MINING PRESS *are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.*

Johnson Electric Furnace

The Editor:

Sir—In the *Press* of January 2, I notice an inaccuracy which should be corrected concerning the work of the Johnson electric furnace. Mr. Keeney, in his review of 'Electric Smelting in 1914' (page 26) makes the statement that "much publicity has been given to an experimental run on 17 tons of zinc ore in the Johnson electric furnace at Hartford, etc."

The following are the results of the 42-day run. During this period there was treated 60,525 lb. of ore, yielding 17,245 lb. of spelter, 3478 lb. of 12% copper matte, 2437 lb. of 116-oz. lead bullion, and 45,850 lb. of slag. During this time ores from New Hampshire, Nevada, Colorado, and other western states were treated, having the following range in composition: zinc, 21.75 to 44.1%; lead, 0 to 17.5%; copper, 0.5 to 2.25%; iron, 4.5 to 32.87%; sulphur, 0.15 to 6.23%; lime, 1 to 3.8%; alumina, 1.13 to 8.5%; insoluble, 8.37 to 20%; silver, 2.6 to 23 oz. per ton; and gold, 0.04 to 0.4 oz. per ton. The recovery of zinc for the entire run was 86.1%. Spelter produced direct was 77.87%. The electrode consumption per ton of ore treated was 6.05 lb. Arrangements have been completed for the erection of the first 10-ton furnace of a 100-ton commercial plant.

JOSEPH STRUTHERS.

New York, January 12.

Precision of Thought

The Editor:

Sir—Of course, you have my cordial sympathy in your effort to obtain clarity of expression by your note on 'Precision of Thought.' The good humored attack of W. S Prosser will have left you, I trust, undismayed. The subject came to my mind this morning in reading the American note, couched in terms of exemplary frankness and courtesy, to the British government, on contraband of war and the searching of ships trading with neutral countries. In that note, signed by the American Ambassador, who, I may add incidentally, fully maintains the peculiarly fine traditions of his honorable office, there is a curious confusion in the use of the singular and plural in respect of the idea denoted by the word 'Government.' In the text as published in our morning papers it is stated variously:

"The Government of the United States *have* viewed, etc."

"This Government *has* so often exhibited."

"The British Government *were* satisfied."

"This Government *is* forced."

"The Government of the United States *do* not intend."

"This Government *is* informed."

"The Government of the United States *are* informed."

"The Government *believes*."

"The Government of the United States *expresses*."

Apparently the singular and plural forms are employed with impartiality. I submit to you that the Government *is* a unit; it represents the administration as an entity. The members of the Government *are* united for the purposes of national administration.

In England the same mistake is equally common. Papers and politicians often speak of the Cabinet, the Ministry, and the Government in the plural form, although each of these words connotes the idea of unity. The Cabinet *is* a select committee of the party in political control, the members of the Cabinet *are* men of various aptitudes. The United States *is* a great country; the United States *are* more numerous than at the time of the Civil War, and so forth. Undoubtedly the discriminating use of the singular and plural forms facilitates clearness of thought, and, therefore, of expression. That is why the difference of form was evolved.

T. A. RICKARD.

London, January 1.

Solution Control in Cyanidation

The Editor:

Sir—Mr. Harai Layng's contribution to the above discussion in your October 17 issue would have been more to the point had he chosen to criticize the alkalinity method used in my series rather than to condemn a method which, after much experimenting, I had previously decided was unreliable, and which I neither mentioned in my article nor in subsequent discussion.

Mr. Layng, after correctly summarizing the scheme of tests I advocated, adds: "That this method is doubtful may be proved by the following: In the first step of Mr. Allen's method, where he adds caustic alkali before titrating for total cyanide, the following reaction would occur:

(1) $2KCN + AgNO_3 = KAg(CN)_2 + KNO_3$

(2) $K_2Zn(CN)_4 + 4KOH + 2AgNO_3 = 2KAg(CN)_2 + Zn(OK)_2 + 2KNO_3 + 2H_2O$."

As these equations appeared, with acknowledgement, in my original article, it is obvious that, so far, Mr. Layng agrees with me that the addition of alkali to a

working solution containing the double cyanides does not necessarily regenerate free cyanide, and that the ordinary Liebig test, with KI as indicator, is useless for determining free cyanide content.

The criticism then continues: "In the tests for protective alkalinity he does not add any caustic alkali, but adds the same amount of $AgNO_3$ to it before titrating for protective alkalinity as he added to his test for total cyanide." The need for adding caustic alkali to a cyanide solution before testing for protective alkalinity certainly did not strike me as a sane procedure, but let me state that I do not add the same amount of $AgNO_3$, but an excess (in amount to be determined). This fact is of importance, and I cannot understand why Mr. Layng should take the trouble to state a fact in his preamble and omit it when he criticizes in detail.

Mr. Layng continues: "If his solutions contained no protective alkalinity the following reactions in the case of the $K_2Zn(CN)_4$ would occur on the addition of the same amount of $AgNO_3$ as was added to his total cyanide test:

$$(3)\ K_2Zn(CN)_4 + 2AgNO_3 = 2AgCN + Zn(CN)_2 + 2KNO_3."$$

The equation is no doubt interesting, but the point is foreign to the present discussion, and the reaction shown cannot and does not occur in, or as a preliminary to, the alkalinity test I outlined. In the free cyanide test the addition of KI insures the selective reaction resulting in yellow opalescent AgI in preference to the precipitate of silver cyanide.

Mr. Layng continues "But if the solution contained some protective alkalinity, though not sufficient to supply the alkali for the reaction (2), the result of adding the amount of $AgNO_3$ found necessary for the total cyanide would be the formation of more or less alkaline zincate, according to the amount of caustic alkali contained in the solution." The point which Mr. Layng entirely ignores is that *potassium ferrocyanide is added before the $AgNO_3$*. It is again a curious coincidence that whereas in his summary he acknowledges that I am using Green's alkalinity test, when he comes to detailed criticism he discusses another test altogether. The use of ferrocyanide is the crux of Green's test, and by its addition before the $AgNO_3$ the formation of alkaline zincate is avoided. The equation, according to Bettel, is:

$$2K_4Fe(CN)_6 + 3K_2Zn(CN)_4 = K_2Zn_3Fe_2(CN)_{12} + 12KCN.$$

The excess of $AgNO_3$ subsequently added renders the solution neutral by the formation of $KAg(CN)_2$.

The remainder of Mr. Layng's criticism deals at length with his opinions as to the behavior of zincates in cyanide solutions, but as he also suggests that the zinc in a working solution may exist entirely as double cyanide, his remarks lose force. He concludes by suggesting that I did not prove that zinc does not exist in solutions (in general?) as a zincate of an alkali. Having attempted no such impossible task, I agree with Mr. Layng. What I did prove by analysis was that, in the solution in question, the tests outlined gave substantially accurate results as an alternative to Liebig's test with KI indicator, which gave no true measure of free cyanide content.

Mr. Layng confuses the theoretical considerations as to what would happen if caustic alkali were added to neutral potassium-zinc-cyanide solution with the practical question as to the result of the addition of alkali to a working solution carrying zinc as the double salt and protected with free cyanide. In the former case a certain amount of dissociation will undoubtedly result, but, as I maintain, not in the latter. If Mr. Layng will refer to the original article he will find that all my tests were made with working solution.

An impression is common that the double cyanides only act as solvents for gold after the addition of alkali. Mr. Layng subscribes to this belief and states boldly that "zinc double cyanide * * * would not be available for extraction purposes unless it should be treated with caustic alkali." As an argument in favor of the alkaline regeneration theory it is worthy of attention, but I am unaware that it has any foundation in fact. Goyder's results are, I think, conclusive. He states*: "I prepared some of these double cyanides and purified them by crystallization, several times repeated, and found that zinc-potassium-cyanide dissolves gold in the presence of oxygen and produces gold-potassium-cyanide and oxide of zinc." The equation is as follows:

$$K_2Zn(CN)_4 + Au_2 + O = 2KAu(CN)_2 + ZnO.$$

In practice it has been found that the presence of the double cyanide seldom adversely affects the efficiency of result. With regard to the effect of the addition of alkali, it has been shown by Julian and Smart† that the increase in dissolving power is almost the same with a solution of KCN as it is with a solution of $K_2Zn(CN)_4$.

Where the zinc double cyanide does make itself felt is in the precipitation department, an excess of the salt lowering the efficiency of this part of the process unless a proportionately high free cyanide strength is maintained, which results in an increased consumption of solvent and precipitant.

A. W. Allen.

London, December 23, 1914.

Bucket Elevators

The Editor:

Sir—In the article on the Plymouth mill which appeared in your issue of October 31, Mr. Caetani mentions trouble with the head pulley of bucket elevators. On similar work under most exacting conditions I have used the following arrangement: A pulley with a solid hub, bored to take a taper wedge similar to the Blanton cam fastener. Such a pulley needs no attention after once being placed in position.

William Seward Mann.

Cisco, California, December 15, 1914.

Chemical News, Aug. 23, 1895.

†'Cyaniding Gold and Silver Ores,' p. 105.

CONCENTRATES

Readers of the MINING PRESS *are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.*

A SILVER-TIN LODE is being mined at the Aramayo Francke property in Bolivia. This peculiar ore is shipped to England, but a lixiviation plant is to be erected to treat it locally.

TRANSIT SHOTS amounting to 600 were taken in eight hours by a surveyor with the Morgan Engineering Co., of Memphis, Tennessee, during 1914. This is a record for topographical work. A Berger transit was used.

THE FUEL VALUE of 2 lb. of wood is roughly equivalent to that of 1 lb. of coal. This is given as the result of certain calculations now being made in the Forest Service laboratory of the U. S. Department of Agriculture.

WOODEN CROSS-TIES used by steam and electric railroads in the United States totaled 123,751,000 in 1909, at a cost of $60,320,700. Of these ties, 16,437,000 were required for new construction and 107,314,000 for renewals.

TUBE-MILL AND CLASSIFICATION PLANT at the Champion Reef mine, India, started on September 26. It consists of three 4-ft. 9-in. by 19-ft. mills, fitted with ribbed manganese steel liners. Classification is done in two primary cones, 5 by 7 ft. 6 in. each, and six secondary cones, 7 ft. 3 in. by 9 ft. each. Two 6-in. and one 9-in. air-lifts are used for elevating pulp in the plant.

'SAFETY FIRST' of the Nevada Consolidated Copper Co. shows the following results of this work in the past two years:

Men employed at—	1913.	1914.	Reduction, per cent.
Veteran mine, underground	304	144	52.6
Copper Flat, open pit	581	490	15.6
Steptoe concentrator and smelter	1584	1214	23.3
Average number men employed daily at all operations	2469	1848	25.1
Fatalities:			
Number of accidents	11	4	63.6
Men killed	13	8	38.5
Disabling accidents:			
Men injured	399	173	56.6
Days incapacitated	4933	1807	63.4

The reduction of 'safety first' from a crude abstract to a tangible reality can be accomplished by concentrating your thoughts on safety; roasting to a friable state all refractory opposition to safety; reverberating the slogan till its echoes make careless men think of safety; and converting your careless habits into habits and thoughts of safety.

SAFETY FIRST CAMPAIGN was started by the Anaconda Copper Mining Co. on January 1, 1914, and has resulted in a reduction of the number of accidents, according to J. J. Corrigan, safety engineer. Fatalities were reduced about 50%, yet greater care by the men is needed. In the mines at Butte, figures compiled by the Company show that accidents occur from various causes in the following percentages: Fall of ground, 43.21; caught by mine cars, 12.97; handling tools, 14.54; handling material, 11.87; falling, 10; falling timber, 3.62; explosives, 0.70; machinery, 1.11; around cages, 0.74; and miscellaneous, 1.24 per cent. Falling in chutes, a form of accident which heretofore resulted in about 10% of the fatalities, has been greatly reduced, and if all will obey the rules which are now in force this class of accidents should be almost entirely eliminated.

CONSIDERABLE INJURY in mines and mills may be traced to the use of loose-fitting wrenches, splintered or broken shovel handles, and other uncared-for hand tools. The largest contributors to injuries in the latter class are chisels, punches, wedges, blacksmith's tools, stonecutter's tools, and similar small hand tools which are subjected to frequent hammer blows, in consequence of which their heads become readily 'mushroomed.' A mushroomed head presents a dangerous condition, for the next hammer blow may break off one of the slivers of steel hanging to the body of the tool and send it flying through the air with great risk of injury to the man handling the tool or to others nearby. The remedy costs little, is well known, simple, and effective. When the head of such a tool is found to be chipped, cracked, or mushroomed, it should be promptly laid aside and not used again until the head has been ground down or dressed to its proper shape. A good practice applicable to cold-chisels and other tools that must be sharpened frequently is to grind down their heads every time the tools are sharpened, thus preventing the development of a mushroomed condition, at the same time retaining the hammer-hardened ends which will not spread so rapidly in the future life of the tools; this practice also avoids much waste of the steel which would otherwise have to be cut off if the heads of the tools were re-forged. As a further precautionary measure, all steel hand tools that are likely to be struck by hand hammers or sledges should have the upper part of the shanks shaped round, and slightly tapered from the top downward, before they are used; care should also be taken to make such tools of the right grade of steel, else the battered overhanging portions of the tools will readily break off.

FLAT CREEK, SHOWING YUKON GOLD CO.'S DREDGE.

MINING IN THE FAR NORTH*

The Iditarod District—Dredging and Placer Operations

By EMIL EDWARD HURJA

The Iditarod mining district is about 150 miles southwest of the Ruby district, which was reviewed in the *Press* in the preceding article. It comprises the streams flowing into the Iditarod river. Most of the producing creeks head into the dike mass cut by Flat creek. The first gold in the Iditarod district was found in 1909 and the few years following that were marked by a great inrush of people. The rush and reports of fabulous placers attracted engineers of the Yukon Gold Co., a Guggenheim corporation, which obtained options on many claims and conducted thorough prospecting. Because of the inability to arrive at satisfactory terms with the owners of the ground, the taking over the ground was not completed until the winter of 1911-12. In the summer of 1912 a dredge was dismantled at Dawson and taken to Iditarod, to be hauled to the Marietta Association claim on Flat creek. Its coming put an end to most of the old-time placer mining, where the individual reigned supreme. The small plants that used to line the creeks and employ hundreds of men gave way to the dredge, with its picked crew.

The general relief of the district is low, although high hills in the region are not uncommon. They are the result of igneous intrusions. There are three settlements in the Iditarod district. One is the town of Flat, situated at the mouth of that creek. The other is the town of Iditarod, situated at the head of navigation on the Iditarod river. The third is the town of Discovery Otter, on a claim of that name. In Iditarod the 1911 production was about $3,000,000, compared with $825,000 during the summer of 1910. In 1912 and 1913 about $2,500,000 to $3,000,000 was produced. The winter of 1910-11 marked the first transportation of gold from Iditarod to the coast by dog-team. This was necessary as the mining season continued until the season of navigation had closed and the clean-ups of the month or six weeks had to be carried outside overland. The development of Iditarod has been hindered to some extent by the early practice of staking association claims, thus blanketing large areas of possible gold-bearing ground and withholding it from development. The Iditarod ground usually is shallow, and the operations are conducted by open-cutting. Considerable attention has been given of late to the Kuskokwim district, which adjoins the Iditarod. Drills have been taken over from Iditarod, and plans for dredging enterprises are said to have been recently completed.

The principal gold-bearing streams of the Iditarod camp are Flat creek, tributary to Otter creek, and Otter creek itself. Some mining has been done along Glen gulch and Black creek, as well as Happy gulch and Willow creek. By far the greatest production has come from Flat and Otter creeks, on each of which a dredge worked last year.

At the extreme head of Flat creek, on the hillside, Strandberg & Aitken are ground-sluicing into the boxes, using a 3-in. nozzle in the work, and a 16-hp. steam derrick to hoist the big boulders. Aitken also has a crew of 30 men working on the Mading bench claim on the left limit of Flat creek opposite the Yukon Gold Co.'s dredge. The gold occurs mostly in bedrock, so the overburden must be ground-sluiced off. The streak has a width of 150 ft. The 'pay' is hoisted on a dump, to be sluiced through three strings of boxes underlying it when water conditions permit. An automatic dam controls the water for the claim. Aitken's operations on Idaho creek, a tributary of Flat creek, are conducted only when water conditions permit sluicing to be done. The Yukon Gold Co. dredge is operating on the Wildcat ground. Its operation was touched upon more in detail in the article

*[Previous articles in this series by Mr. Hurja include a general survey of the mining situation in the more important districts throughout Alaska.—EDITOR.]

STEAM POINTS THAWING GRAVEL AHEAD OF RILEY & MARSTEN DREDGE.

dealing with the operations of the Yukon Gold Co. which appeared in the October 10, 1914, issue of the *Press*.

On the upper end of Discovery claim, Otter creek, Riley & Marsten completed the installation of a gasoline-operated dredge early in the summer. The dredge was built by the Union Construction Co. of San Francisco. It cost $80,000, including the freight to its final destination on Otter creek. A 12-mile haul from Iditarod was necessary. Freight from San Francisco was $80 per ton. The dredge has 3½-ft. buckets and a daily capacity of 2000 yd. It is operated by two 60-hp. Union gasoline engines. The dredge started operations May 27, 1914. It had worked downstream a distance of 100 ft. by September 1, working the ground for the whole width of the claim. At present the dredge is on the Beaton ground on 1 Below, Otter creek.

Riley & McMillan, working on 1 Below bench claim on the left limit of Otter creek, started work on June 15. They are scraping with a three-drum hoist and a battery of boilers with 50 hp. capacity. A three-inch nozzle was used to clean off the 'muck.' The ground is from seven to ten feet deep, with the 'muck sheet' ranging from four to five feet in thickness. A Bagley scraper is used. It unloads the dirt into a car which runs up an incline to the dump box. On August 15, 85,000 sq. ft. of ground had been cleaned up ready for scraping into the boxes, and it was expected this amount could be worked easily before the season came to a close. For next season's work, 150,000 sq. ft. of 'muck' has been removed from virgin ground. This was possible because of the abundance of water this summer. Twenty-two men were employed throughout the sluicing season on the claim. Pole riffles with iron straps of half-inch iron are used in the sluice-boxes to save the gold, with one undercurrent of perforated iron plates and cocoa matting to catch the finer particles.

Bates Brothers, on Discovery bench on the left limit of Otter creek, have ground-sluicing in progress as well as the scraping of waste gravel. When the work of sluicing started, fifty men were put to work. The dirt is shoveled into wheel-barrows, which are dumped into buckets. The dirt is hoisted from 8 to 14 ft. to the sluice-boxes. The season's output was in excess of 80,000 sq. ft. Riley & Marsten are working on the creek claim, on Discovery claim, Otter creek, with a three-yard scraper and a 90-hp. donkey engine. The dirt is scraped into a car which travels 25 ft. to the sluice-boxes. Where the bedrock is hard, the 'pay' is shoveled into wheelbarrows, to be hoisted in buckets to the top of the cut into the sluice-boxes. As considerable gold occurs in bedrock, sometimes as much as five feet of the bedrock is taken out. Sixty men were working during the summer. The season's probable output was placed at from 47,500 to 50,000 sq. ft. Frank Dawson is operating on Crane gulch, a tributary to Otter creek. Crane enters Otter on the left limit at Discovery. Three miles of ditch has been built from the head of Slate creek, which delivers water to the 3-in. nozzles with a 90-ft. head. The nozzles are used to strip the ground of 10 ft. of 'muck' which covers four feet of 'pay-gravel.' The gravel is hoisted to the top of the cut, a distance of 16 ft., where the boxes are placed. The 'pay' averages $1.50 per sq. ft. The season's output is estimated at 10,000 square feet.

John Olstrom and Frank Hurkos, working on the left limit of Otter creek, on No. 2 Above, bench claim, worked 28,000 sq. ft. of ground during the summer. The ground is 22 ft. deep. Twenty feet of 'muck' and waste gravel was ground-sluiced off, the rest shoveled into the sluice-boxes as 'pay.' Shield & Neumier did not have as good a season as they expected on the upper end of No. 2 Above, left limit bench claim, because of a scarcity of water for sluicing operations. Ten men were employed. Gravel was hoisted from the cut to the sluice-boxes above. 'Red' Ellis worked on No. 2 Above, creek claim, during the summer. He took out a fair-sized block of ground and expects to work next season for a time. Louis Stetzer and George Riley are working on the upper end of No. 2 Above, creek claim, with a scraper operated by a 60-hp. donkey engine. A 6-in. centrifugal pump is used to supply water for the sluice-boxes during dry weather. The season's output is given as 200,000 sq. ft. Forty men are employed when the operations are on bedrock. Usually the crew consists of from 10 to 12 men.

On Black creek, Fred Smith and Olaf Olson had a crew of 10 men working a greater part of the summer. The gravel was hoisted from a depth of 12 ft. The first cut was 8000 sq. ft. in extent. It averaged 60c. per sq. ft. A second cut of 10,000 sq. ft. was completed before the end of the season. Many other plants operated in a small way on the other creeks surrounding Iditarod. Considerable prospecting was done last winter, and reports are that even more will be done the coming winter, because the depressed fur market will drive trappers to take up prospecting for their winter's work.

RILEY & MARSTEN DREDGE, OTTER CREEK, IDITAROD.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

KALGOORLIE, WESTERN AUSTRALIA

STATE GOLD RETURNS IN 1914 A DECREASE.—EDNA MAY, GREAT BOULDER, HORSE-SHOE, CHAFFERS, IVANHOE, AND OTHER MINE DEVELOPMENTS.

The year 1914 has been a disappointing one for gold mining in this state, and the total output is not likely to exceed $26,000,000, against $27,908,000 in 1913, and $27,318,000 in 1912. No new discoveries of any importance have been reported, and, in many cases, there has been a steady decline in the yield of certain districts. The chief exception to this depressing state of affairs has been the Edna May, at Westonia, a mine which owed its discovery to the widespread prospecting caused by the Bullfinch boom of 1910-1911, during which the adjoining mine, taken up by the Greenfinch company, was located by Frank Weston early in 1911. The lode in the Greenfinch area, although containing $20 per ton, was intruded every few feet below 50 ft. by successive horizontal bands, or floors, of granite, which cut through it without either displacing the lode or affecting its value. Eventually, however, solid granite was met with, which completely cut off the lode before a depth of 100 ft. was reached, and all operations were suspended. Owing to this fact, geologists

THE MEEKATHARRA FIELD AS SEEN FROM THE INGLISTON EXTENDED. A PROMISING DISTRICT WHICH PRODUCED $1,500,000 FROM 129,123 TONS IN 1913, AND ABOUT $12,500,000 FROM 850,000 TONS TO THE END OF 1914.

and mining engineers have been extremely cautious in expressing an opinion regarding the continuation in depth of the Edna May lode, and this is still a question.

The mine which has best maintained its position during the year is the Great Boulder, which, during the expired 10 months, has yielded $2,494,100, and earned $1,165,100 in profits, against $2,364,100 and $1,124,600, respectively, in 1913. This mine has ceased sinking for three years since the lode passed into the property of the Golden Horse-Shoe. Recent drilling from the Perseverance into the Boulder has been of considerable importance.

Regarding the Horse-Shoe mine, a practically new area is being opened up in the south end of the claim from the 1300 to the 2000-ft. level, where the ore-shoot has been proved to gradually lengthen as far as Chaffers boundary instead of becoming barren 600 ft. from it, as in the upper levels. In addition, developments on the Great Boulder main lode between the 2480 and 2900-ft. levels prove that high-grade ore, containing telluride and free gold in places, continues. At 2900 ft. the shoot in the north end has ranged from $31.60 to $66.26 per ton for the full width of the drift, and, in the south end, from $10.20 to $10.70 per ton. The width of the lode, where cross cut at this depth, is 15 feet.

Regarding Chaffers, the first return of 6138 tons for $27,500, and a loss of $5500, is distinctly disappointing even if, as officially stated, $10,000 was absorbed by the plant. The Company finances are somewhat strained. With the exception of a shoot 181 ft. long, worth $25.80 per ton, in No. 3 west lode at No. 16 level, the average of the ore opened up is no better than that treated prior to the reconstruction of the Company, or say $6.50 recoverable, and the profit is not likely to exceed 60c. per ton. The money raised was for exploring the mine to a greater depth for the continuation of the Golden Horse-Shoe shoots, as advised by John Morgan; but this was not done, and a further reconstruction is probable.

None of the other mines on the Golden Mile has improved its position, but the Ivanhoe is still sinking and is down 3215 ft., and the Lake View & Star is developing well in the Star property.

During the year the Great Fingall, Bullfinch, and Victorious have proved disappointing. This is especially the case with the Great Fingall, as the grade of ore treated since the mill resumed operations has only averaged $6.84, against $9.40 per ton estimated, and the 40-stamp mill has only run about half time. With regard to the Victorious, it seems doubtful whether the Associated Northern Co. will recover the $105,000 spent on development and equipment since treatment stopped for erection of the sulphide mill.

The Oroya Links report for the third quarter of 1914 shows that 37,300 tons of ore yielded $5.06 per ton, and a total profit of $14,500. Working costs totaled $3.89 per ton.

NEW YORK

NEW KEYSTONE-INSPIRATION AFFAIRS.—COPPER RANGE CONSOLIDATED COPPER.—COPPER COMPANIES, DIVIDENDS, STOCKS OF METAL, AND EXPORTS.

The proposal to consolidate the New Keystone with the Inspiration was carried by a small majority of the stockholders at a meeting last week. The matter is, of course, not completely settled yet, for it is possible for a disgruntled minority to make almost indefinite trouble in a legal way, as is seen in the case of the litigation against the Old Dominion. There seems to be some hope, however, that the insurgents may be reconciled and the consolidation proceed quietly. It is said that troubles never come singly, and a further difficulty developed when the labor dispute arose which was dealt with in the *Press* of last week and the current issue. Construction work is so near completion on the Inspiration and the smelter, that the strike was not very serious as far as they are concerned, because as long as copper remains at its present low price there seems to be no particular incentive to start them.

The Copper Range Consolidated changed its selling arrangements a short while ago, and its copper, which formerly was sold by the United Metals Selling Co. will now be marketed by the Copper Range itself. The United company now has no Lake copper to sell, as the distinction between Lake and electrolytic copper has yearly been growing less, and is not nearly so strong as it used to be. The Copper Range copper has a

peculiar market of its own, as it contains just enough arsenic to make it especially suitable for the making of tubes, the rolling of sheets, and various other special purposes for which it is finding a ready market without any difficulty.

The directors of the Shattuck-Arizona Copper Co. have resumed dividend payments, and 50c. per share will be paid February 20 ——Amalgamated Copper has also resumed dividends with a 50c. quarterly payment.——The Calumet & Arizona board of directors has created a committee of three to handle all the details of the financing of the Ajo property. Work on the method of leaching to be adopted is well advanced, and it is probable that some announcement will be made before long. The Granby Consolidated has blown in four of its furnaces at Grand Forks, while two are running at Anyox.——It was reported that the Calumet & Hecla was to resume dividend payments, but a statement by the vice-president of the Company states that the matter has not even been discussed by the directors, and unless the price of copper improves before the end of March, it is not probable that there will be any distribution at present.

Consumers of copper are insisting that the producers will increase their output soon, while the producers fail to see the necessity of any such move. The National Conduit Co. has calculated that on January 1 the stocks of refined copper amounted to 223,000,000 lb., which scarcely indicates any necessity for an increased yield. What producers are asserting their strategy for, is to get prices up to a point at which there is some possibility of their making profits on operation before increasing their output. Consumers, of course, are interested in doing everything they can to keep prices down to the lowest level possible. That is, of course, to their advantage, but it is very much to the disadvantage of the copper mining industry and therefore to the country as a whole.

Exports of copper from New York for the week ended January 2 totaled 12,000,000 lb., and for the week ended January 9, 16,000,000 lb. Exports from New York for the seven weeks ended January 15 amounted to 70,400,000 lb. Russia has been buying copper lately in considerable amount, and it is reported that some of the shipment will be sent to Japan, where it will be manufactured into munitions of war for the Russian army. The story seems highly improbable, since copper has been ruling at a very low price in Japan for some time, as some of the Japanese copper comes to this country for refining. The story illustrates the many improbable statements that are made concerning conditions while the war prevails. In Germany the National Council has fixed a maximum price for refined and scrap copper. This, of course, only applies to dealings within the country to prevent unscrupulous dealers from taking advantage of their fellow countrymen, but will not serve to restrict the prices that German consumers might pay in order to get copper from outside. There have been no developments of importance in regard to the question of exports of copper in the past week, and the matter has simply become one of the various questions to be considered in connection with the protest which the U. S. government has made to England in regard to American shipments.

TORONTO, ONTARIO

The Nickel Controversy Again.—Hollinger Dividends, Mill, Air-Compressors, and Future.—Porcupine Crown, McIntyre, Hurionia, and North Thompson Mines.—Cobalt Silver Production.

The controversy regarding the ultimate destination of nickel, refined from Canadian ores, still continues, although official statements by Sir Robert Borden, premier of Canada, and Ambrose Monell, president of the International Nickel Co., have definitely refuted the allegations made against the Company. Mr. Monell stated that there was no nickel being shipped to Germany or its allies, and that there was no foreign influence in the affairs of the Company, as had been given out by a considerable proportion of the influential Canadian press. The statement by the Canadian government was to the effect that it, acting for the British government, was thoroughly in touch with the situation, and was kept constantly informed regarding all shipments of nickel, whether for domestic or foreign consumption. An auditor, acting for the government, regularly inspects the books of the International Nickel Co. to see that the information regarding shipments is correct. It was further stated that an examination of the list of shareholders showed that the majority of shares was held in the United States. The British government also has expressed itself as being satisfied with the precautions taken. While in the beginning this agitation arose from a genuine fear that Ontario nickel was being sent to Germany to be used in the manufacture of munitions of war, the belief is now growing that the present continued stirring up of this subject is an attempt to drag the matter into the realms of party politics, and that this attempt is being fostered by those who are interested in the sale of nickel properties which are at the present time unsalable. The agitators have already demanded that all the nickel be refined in Canada, and the next move in the game will probably be that a bounty be paid for nickel so refined. If those interested were successful in getting what they want, they would have a much greater opportunity to dispose of the properties which they have been so long unsuccessfully trying to market.

The rapid and continued rise in Hollinger shares has been the outstanding feature of the mining market for the past few weeks, and is explained by the action of the directors in increasing the dividend, as mentioned in the *Press* of January 23. Present earnings seem to justify the increase, and with the new addition to the mill which is nearing completion, profits should be maintained even with a considerably lower grade of ore. It is understood that the intention is to keep on gradually adding to the capacity of the mill as development progresses on the Hollinger, Acme, and Miller-Middleton, which are all controlled by the Canadian Mines & Finance Co., with the idea of ultimately arriving at a capacity of 3000 tons per day. Before this stage is reached, however, the three properties will be consolidated. The large central plant for supplying compressed air to the three properties is nearly finished. At the present time one Fraser & Chalmers and two Nordberg machines, each having a capacity of 5000 cu. ft. of free air per minute, are in operation, while a third Nordberg machine of equal capacity is being installed.

The Dome company has placed an order for a 36 by 48-in. jaw-crusher, to be installed in the bottom level of the mine.

After a great deal of prospecting, the Porcupine Crown company has succeeded in locating the extension of its main vein below the 500-ft. level, and the drifts being opened on the ore show that it maintains its usual width and value. About eight months ago, in sinking below 400 ft., the vein cut out, and although a large amount of work had been done with a view to finding the continuation, it was only recently that the Company's efforts met with success.

The McIntyre has started sinking the main shaft from 500 to the 600-ft. level. Recent developments have been satisfactory, and the Company expects to be able to maintain a monthly output of between $60,000 and $70,000.

The Hurona mine, in the Larder Lake district, recently shipped $3000 as the result of a two weeks' run. The Company is now receiving power from the plant of the Goldfields, Limited, and expects shortly to be in a position to operate the mill regularly. The results being obtained on the Huronian have resulted in two adjoining claims being taken under option by the Trethewey company of Cobalt.

The North Thompson Associated Gold Mines, Ltd., is the somewhat lengthy name of a new company, recently regis-

tered in London, which will operate the North Thompson properties in Porcupine, taken under option by Erlich & Co. about a year ago. The new concern has a capital of £200,000 in £1 shares and it will make an agreement with the Associated Gold Mines of Western Australia, the parent Company regarding the Porcupine property. Directors are to receive £100 per year salary and 5% of the profits, with a maximum of £1000 per year.

It is expected that the output of silver from Cobalt in 1914 will be about 23,000,000 oz., a decrease of 5,000,000 oz. from the preceding year, and a decrease of about 10,000,000 oz. compared with the record year of the district. This falling off is due in part to the lower prices for silver and to the fact that when the war started several of the mines were closed down, but it is also partly due to the gradual exhaustion of the mines themselves. The year 1915 will probably show further decreases, as some of the mines are having a hard struggle to maintain the present rate of dividends. In these properties the ore reserves are practically depleted, and the possibilities for further discoveries are not promising, so that it is only to be expected that some mines will close permanently during 1915.

LORDSBURG, NEW MEXICO

Recent Ore Shipments from Lordsburg, Bonney Mining Co.—Mogollon.—Ore Treatment Problems at Pinos Altos.—Sierra County Mines.—Steins.—Burro Mountain Mine.

The month of December in the Lordsburg district was one of the smallest, as regards ore shipments, in many years. Constant rains, making ore freighting impossible, was the cause. According to official reports, the total was 40 cars, 150 cars being the average during curtailment. Starting January 5, operations on a large scale were resumed at the 85 mine, it being possible to haul ore to the A. & N. M. railroad. A night shift has been added to the working forces.

At the annual meeting of the Bonney Mining Co., held at Lordsburg on January 1, it was decided to sink No. 3 shaft to a depth of 511 ft., drive on the 300-ft. level to No. 2 shaft, and explore intermediate ground. The new power plant at the No. 3 mine is in operation and is supplying compressed air for operation of hoist and drills at the No. 2. Work will continue at the latter mine, and shipments made from the vein now being operated. Shipments will probably average 12 to 15 cars per month.

Trains from Lordsburg to Clifton and Morenci, Arizona, are now running on schedule time, the wash-out between York and Sheldon being repaired. Traffic to these places was congested on account of the Gila river floods.

Mogollon, in Socorro county, suffered for the lack of supplies during the high-water period. Cableways were washed downstream, and mail was transferred from bank to bank at a great risk of life. Conditions are at the present time such that traffic is being carried on in safety. The Socorro Mining & Milling Co., of Mogollon, has asked the state engineer for an extension of time in which to complete its power project on Whitewater creek. This was granted and the time extended until January 25, 1917. Unforeseen difficulties and increased expenses are the causes assigned for the delay in completing the project.——No word has yet been received of M. Cooney, a pioneer Mogollon mining operator, and one of the regents of the New Mexico School of Mines, who is believed to be lost in the Mogollon mountains. Many searching parties are out. He has been missing since October 25.

Stauber and Wright, who hold a lease on the property of the Savannah Copper Co., are considering the erection of a mill on the Pacific No. 2 property to treat the complex Pinos Altos ores, containing zinc (sulphide), copper, gold, iron pyrite, and silver. This has been attempted many times, but each time was a failure. The Empire Zinc Co. has solved the problem of the Cleveland and Otter zinc sulphide ore but the gold-bearing veins are still to be solved. It is claimed that the lessees will be compelled to erect some kind of an ore-treatment plant, this being a condition in their lease. This statement, however, is unconfirmed. The high-grade gold content of Pinos Altos ore is as formerly.

Work is progressing in the Snowstorm mine at Kingston, Sierra county, and some manganese ore is being developed.

Lessees on the Lookout mine report prospects as being favorable. The Southern Cross mine is again being operated by J. W. Jensen. Carter and O'Neil are developing properties in Pickett Springs gulch.——The Illinois and Saratoga mines at Kingston have been sold to C. T. Brown, of the Empire Zinc Co., for $5000, according to court records. The properties were large producers in the early days, but have been dormant for some time past.

CRUSHER STATION OF CHINO COPPER CO. AT SANTA RITA, NEW MEXICO.

Occasional shipments of ore are being made from Steins, near the Arizona border, by the November Mining Co. and the National Gold & Silver Co.——Free gold has been uncovered in several places near Steins by claimholders doing assessment. Work in the Steeple Rock district has been retarded by the Duncan bridge being washed away during the Gila river floods. Supplies are being sent over the stream by cableway.

According to reports from Tyrone, Phelps, Dodge & Co. will complete the first unit of its 1000-ton capacity mill about the middle of January. Work is progressing fast at the Burro Mountain property, and the mining forces are expected to be doubled in 15 days. Thomas Parker, well known in Tyrone, has given $25,000 for the erection of a hospital in the camp, the Burro Mountain Copper Co. to furnish a similar amount.

PETROGRAD, RUSSIA

Russian Copper in 1914: Factors Influencing Output, Figures for Eight Months, and Estimates for the Year.—By-products from Smelters.—Lead Resources of Russia.

The probable effect of the war on the copper industry of Russia is difficult to determine. It is subject to two influences: first, the great demand from the military point of view, and second, the serious inroads made on the supply of labor for the mines due to the calling of men to the colors. The state of war strikes the industry at a moment when it is in a very unpromising condition. In the past few years copper production of the country has grown surprisingly fast, and it was freely prophesied that the present year would see the end of the importation of foreign copper into the country and the beginning of the exportation of Russian copper abroad.

But last year this growth was arrested. The reasons given might be held to be satisfactory, if all true, namely, that a number of companies had stopped production for the purpose of renewing and extending their plants. Unfortunately, this view had to be taken, however, with a knowledge that the slackening in progress affected more than one important copper-producing district, and it seemed remarkable that the country's industry should have started marking time just at a period when industry generally in Russia was unprecedentedly good, and the demand consequently a large one, and one to be taken advantage of, so that when the inevitable general trade depression should arrive, the alterations, admittedly so much required, could be made. A fresh complication, as far as the Caucasus is concerned, has supervened through the military activity of the Turks, who, it is reported, have got control of the largest Caucasian copper property, which it is said to be the intention of the Russians to promptly recover possession of, if for no other reason than the desire to deprive the Germans of this source of supply of an article of which they stand in such reported urgent need.

Due largely to the business instinct of the foreign element that is so largely exploiting the Urals copper deposits, a development has taken place considerably adding to the value of the business in that district, namely, the manufacture of sulphuric acid from the sulphur fume liberated in smelting copper ore. This will no doubt act and react to the advantage of the industry. There are considerable deposits of phosphates within practicable reach of the copper works, and, in the manufacture of superphosphate, acid had to be brought great distances. But the new sources of acid supply will not only facilitate the existing superphosphate business, but, owing to the cheapness of the acid, the superphosphate production will be stimulated, and so call for more of this by-product of the copper industry. Notwithstanding this, the cessation of operations referred to took place, and has since developed into not only a positive but a very serious setback in the production of copper.

This setback has been progressing in intensity in the chief producing districts during the course of the current year. Thus, in the first six months, the production of copper amounted to 16,112 tons, against 17,103 tons in the corresponding six months of 1913, a decline of 991 tons, or 5.8%. Including July, the total is 18,709 tons, against 19,822 tons, a decline of 1114 tons, or 5.62%. The improvement is accounted for by a better return from Siberia; but, on the other hand, the other districts, Urals and Caucasus—that is, the most important—had declined in a slightly greater ratio. The latest returns received are for the first eight months of the year, including one of the war, namely, August. This shows a total production of 21,061 tons, compared with 22,664 tons in the corresponding eight months of 1913. The decline amounts to 1602 tons, or 7.7%. The slight improvement in Siberia during the first seven months loses its value in the eight months, having declined from 3.41 to 1%. The following table shows eight months' production, in tons:

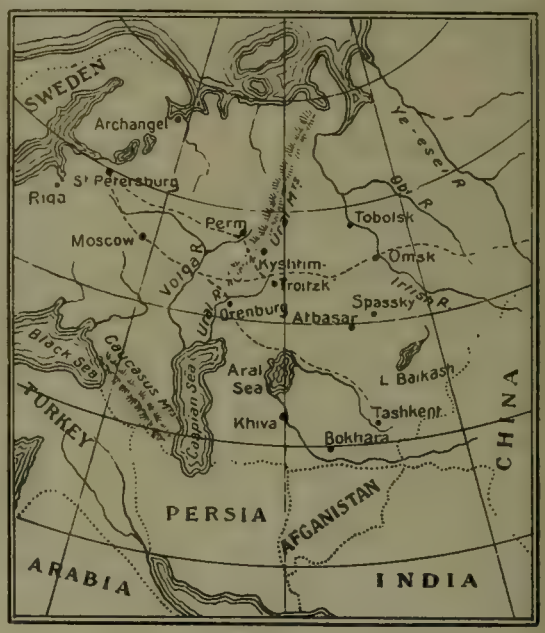
	1913.	1914.	Per cent.
Urals	11,467	10,518	—8.3
Caucasus	6,574	5,946	—9.5
Siberia	3,661	3,700	+1.0
Chemical works and refineries.	9,060	896	—6.6
	30,762	21,060	7.7

These chemical works and refineries produce largely from other than copper ores and recover the copper simply as an associated metal. From this it follows that the production of copper improved only to a slight extent in Siberia, but other production districts show serious declines.

It is interesting to note the estimated production for the year, which was 28,258 tons of common and 11,516 tons of electrolytic copper from the houses that work in agreement, plus about 1129 tons of common copper expected from the Ushkoff and Kreines company. Thus the total anticipated in the past year of all kinds of copper makes 40,903 tons.

The reason given for the decline as suggested above is not altogether convincing. It looks rather as though it were the result of an understanding. It has been persistent, and, as can be seen from the foregoing statement, practically general, and even Siberia now looks like showing a decline when the next returns are issued. Russia, therefore, will probably remain a good buyer of copper, that is, electrolytic copper, for a considerable time to come; for with an increasing population, an improving industrial position, and a declining production, reason points to no other direction.

Owing to military operations, there is a great demand for lead in Russia, and a review of the various domestic sources from which it can be obtained should be of interest. Although the deposits of lead ore on the western shore of



MAP OF PART OF THE RUSSIAN EMPIRE, SHOWING CAUCASUS COPPER DISTRICT AND ARCHANGEL.

Murman, which is on the White sea, east of Varangerfiord, were discovered many years ago, and investigated to some extent by many Russians, including Kamensky in 1875 and Bartanoff in 1889, and again by Povalishin in the nineties, lead mining has not progressed. In the summer of 1903 the right to exploit the mineral was obtained by Nikolaieff; but he did not take advantage of the permission. This deposit required a geological investigation and the expenditure of a considerable sum of money in order to test its value. In 1905 new lodes were discovered, and the examination was in charge of an officer named Stefanovich and a merchant, Edward Ostrem, from the town of Abo. Their work showed the importance of the deposits, and at the present time negotiations are being carried on to organize a company to start proper development. Recently these engineers completed preliminary prospecting and discovered 50 new lodes, of which about 40 are within the area at their disposition. They have rights over 13 areas or lots, of which four are to be worked. In the autumn of 1914 a certain quantity of lead ore was delivered at Archangel, in which town it is proposed to carry on smelting operations.

THE MINING SUMMARY

The news of the week as told by our special correspondents and reflected by the local press

ALASKA

The report of the governor of the territory, J. F. A. Strong, for the fiscal year ended June 30, 1914, has recently been published. The area of Alaska is 590,884 square miles, and the report deals with general conditions, population, railroads and other transportation, forests, reindeer, mines, fisheries, fur, labor conditions, oil, roads, mails, water-power, Indians, future, and a list of operating companies.

KETCHIKAN

(Special Correspondence.)—Just before the European war, many inquiries were made as to the mining possibilities of this district. Several companies began investigations, but as they were financed mostly by foreign capital, operations were suspended when the war started. However, the Granby Consolidated, having secured some good copper and gold properties, will probably resume operations, especially as the copper outlook seems more favorable. The lack of adequate capital and intelligent management for going ahead with development, and not the absence of mineralization, has been the drawback of this district, as pointed out by a recent U. S. Geological Survey report of the Ketchikan district.

The Rush and Brown mine, although under good management, is handicapped by inadequate capital to carry on the mining on a large scale, and is the only copper mine which operated throughout the year in southeastern Alaska.——The Jumbo mine, at Sulzer, discontinued shipment after the fall in copper.——The Granby company is developing the old Mamie mine at Hadley, and expects to ship 300 tons of low-grade and 30 tons of high-grade ore per day from the 'It and Dean,' near Kassan.——Development work was done during the year at Big Harbor, Mt. Andrew, Red Wing, Copper Mount, and other properties.——The Apex and Adit, and Veta claims, between McLean's arm and Mallard bay, are being developed by the owners. Although 2 ft. of ore assaying $7 gold and 7% copper has been opened 45 ft., and over 100 ft. in a large low-grade area adjacent thereto, it will take years to bring this property to the producing stage unless capital can be raised to expedite the work.——Some of the gold properties at Helm Bay, Hollis, Sea Level, and Dolomi are being opened by local capital.

Practically all of the properties in this district are from a few hundred feet to two miles from salt water. Timber and water-power are abundant, and the climate is mild. Operations can be conducted the year round.——Mining and developing companies could no doubt find a profitable field for investment and speculation in this promising district.

Ketchikan, January 7.

ARIZONA

GILA COUNTY

The sequence of events in the labor troubles during the past week are as follows: There are over 1500 men on strike in the Miami district. It is rumored that employees at the Old Dominion mine and smelter at Globe would also come out. The general manager of the Company, P. G. Beckett has addressed a note to the men explaining its attitude. He later said that provided copper sales in January averaged 13c. per pound, an increase to the old rate of May, 1912, would be made in wages from February 1. When the metal rises to 14 and 15c. further increases are proposed for miners, millmen, and smeltermen. Generally, good feeling exists among the strikers. A broken water main at the Inspiration was repaired, and a car of dynamite unloaded. George Powell, president of the Miami Miners' Union stated that the men are ready at any time to submit the dispute to an impartial board of arbitration. Governor Hunt has promised to try to help settle the trouble.

The managers of the Miami and Inspiration companies, B. Britton Gottsberger and C. E. Mills, respectively, have notified the miners that they are willing to take the same action as the Old Dominion company.

Work was resumed at all points on January 24, on account of an agreement as to wages to take effect on February 1. Under the agreement the machinists, electricians, boilermakers, carpenters, helpers, and common laborers will get the

CLAIM MAP OF MIAMI DISTRICT, ARIZONA.

wages that were paid before the 10% cut was made in August. Miners and hoisting engineers will work on a sliding scale. There is to be no discrimination against any of the men on account of the strike. The scale is as follows: machinists, electricians, carpenters, and boilermakers, $4.25; miners, minimum wage, $3.50, with copper at 13c.; $3.65 with copper at 14c.; and $3.75 with copper at 15c. per pound. Hoisting engineers, with copper at 13c., $4.25 on single-drum hoist, $4.50 on double-drum; firemen, $3.75; oilers, $3.50; and pumpmen, $4. With copper at 14c. they will receive a raise of 15c., and at 15c. another 10c. per day will be added to the wages. Laborers, $2 per day. Both the Miami and Inspiration companies are bound by the agreement.

CALIFORNIA

Oil production of the state in 1914 is estimated by the Standard Oil Co. at 103,623,695 bbl., against 97,867,148 bbl. in 1913. The average was 283,901 bbl. per day. Stocks at the end of the year totaled 58,526,274 bbl., compared with 47,870,177 barrels at the end of 1913.

The State Mining Bureau will exhibit at the Panama-Pacific International Exposition, and about 400 sq. ft. of floor space in the Palace of Mines and Metallurgy will be devoted to case exhibits of California's mineral products. Fletcher McN. Hamilton, state mineralogist, will detail from his staff a competent mining engineer whose duty it will be to furnish information to visitors as to the extent and value of the mineral resources. The Bureau would gladly have taken more

extensive part in the Exposition, but the funds were not available, owing to the fact that during the past two years it has been necessary to send engineers over the entire state to gather data for the preparation of a new general report on the mines and mineral resources of the state. The Bureau with its extensive collection of minerals, and the library and statistical department regularly maintained in the Ferry building, will doubtless serve a good purpose in conjunction with its headquarters to be established at the Exposition. All mineral producers wishing to exhibit are invited to communicate with the state mineralogist, Ferry building, San Francisco.

Amador County

A cross-cut out 200 ft. from the 380-ft. shaft at the Hayward mine, three miles from Ione, has cut a wide vein of $6 to $28 copper-gold ore. This old mine was only reopened late in 1913, after being closed for 50 years. The Allen Estate Co. is doing the present development work.

Final returns of the Plymouth Consolidated for December show the following: ore milled, 10,200 tons; value of output, $42,053; surplus in excess of working costs, $19,697; and total costs, $2.687 per ton.

Inyo County

At the Skidoo mine the 10-stamp mill is working. The mine is being developed by adits, three of which have opened about three years' ore, according to the manager, J. H. Cooper. It is proposed to add five stamps to the plant. About 35 men are employed. Costs total $6 per ton.

In Wild Rose cañon, L. C. Mott, of San Francisco, is working an antimony mine and experimental reduction plant. Twenty-two men are employed, and the matte produced contains 93% metal.

Randsburg is reported to have a fairly prosperous appearance, a number of small mines and mills being operated. The Yellow Aster 100-stamp mill is crushing about 500 tons per day.

Shasta County

The Balaklala Copper Co. is shipping three large cars of ore to the Tacoma, Washington, smelter. The last ore sent to that place was in March 1914.——The Russell placer claim at Igo is being prospected by a Keystone drill.

Sierra County

Alleging 40 days' wages is due them, 21 miners at the Twenty-One mine, at Alleghany, have 'downed tools.' G. W. Mitchell is in charge now with five men.

Trinity County

(Special Correspondence.)—Prospects of future mining in Trinity county are bright. During the past year there has been considerable new development, with no shut-downs recorded, and extensive new work is contemplated for 1915. Hydraulicking is holding its own. Quartz mining is steadily increasing, with some good producers on the list, and more probably starting. While the Trinity River area is attracting a great deal of attention for dredging, in the east fork district there is only one property that might be classed as a mine, namely, the Enterprise, which has a depth of about 1300 ft. on the incline. Near it and for five miles to the north and northeast on the east fork, east branch, and Yellow Jacket streams, are to be seen several prospects that look promising. Among them are the Golden Chest, Bonanza, Oversight, and Yellow Jacket. On the three last mentioned, development will prove the orebodies. The Enterprise mine, which has been a producer on and off for more than 25 years, never looked as well as at present. There is 7 ft. of good ore in the face. Ten stamps are dropping 24 hours per day, and 12 men are on the payroll. This mine has produced some high-grade ore during the past three years, and the average was good during 1914. Judging from the present indications, 1915 will be the banner year of its existence. The Globe Consolidated, at Dedrick, has recently cut new orebodies. The mill is treating 125 tons per day.

Helena, January 15.

Tuolumne County

(Special Correspondence.)—It is reported that operations will be resumed at the Santa Ysabel mine during the early part of February, with J. A. Prentice in charge.——B. F. Southerland and others have secured a lease on a portion of the Fleming property from Messrs. Booker and King, and will begin development at once.——A plant is being installed to work the tailing of the App mine, on which D. L. Mann has a long lease. Mr. Mann also has an adjoining claim where he has impounded a large quantity of tailing carried by Woods creek from nearby mines.——Sinking is still in progress at the Black Oak, and it is said to be the intention to continue this work until the shaft has attained a depth of 2000 ft.——Operations have been resumed at the Louisiana mine, near Tuolumne.

Sonora, January 23.

The McAlpine Mines Co. has been organized by San Francisco people to operate the McAlpine group of four quartz claims in the southwestern part of the county. Extensive work has been performed at this group in the past, and much good ore has been extracted at numerous points.

COLORADO

Products of the Colorado plants of the American Smelting & Refining Co., namely, the Globe, Pueblo, Arkansas Valley, and Durango in 1914 are as follows:

Source of ore.	Ore, tons.	Gold, ounces.	Silver, ounces.	Lead, pounds.	Copper, pounds.
British Columbia	5,349	171	166,962	442,122	37,834
*Colorado	573,009	304,723	7,258,427	66,501,208	5,711,714
Canada	4,128	.....	2,417,419	650	44,272
Idaho	80,142	.....	2,816,849	80,818,870	201,209
Montana	558	34	26,598	19,162	9,598
New Mexico	147	767	227	179	2,035
South Dakota	524	979	865	278	3
Utah	1,364	10	1,545	596,558	1,383
Total	665,221	306,684	12,688,892	148,379,027	6,008,048

*This includes ore shipped to other of the Company's plants outside of Colorado.

The total value of all the metals was $19,821,206.

Gilpin County

Steam power at the U. P. R. stamp-mill at Black Hawk has been superseded by electric motors, a 25-hp. driving the crusher and a 50-hp. motor driving eight batteries. Steam is used for the mine hoist and heating purposes.——R. Demeter is manager, and C. Cox, mill superintendent.——The old Happy Five claims near Apex, which have been developed, equipped, and lain idle for many years, are to be reworked.

Lake County (Leadville)

Transformers, motors, and other General Electric equipment have arrived at the Penrose shaft of the Down Town Pumping Co., and the Colorado Power Co. is installing it. The centrifugal pumps will arrive early in February.——The Big Five Operating Co. is to work the Big Four with electricity, and the power company will install an 82-hp. hoist, and 100-hp. compressor, in place of the present steam-driven plant. Olie Strom is manager of the Big Five.

Ouray County

Now that the Wanakah smelter has a capacity of 200 tons per day, that Company and the Ouray press are trying to stimulate prospecting and ore production. Since March 1, 1914, the plant received custom ore weighing 1489 tons, for which $20,952 was paid. Of the 94 lots, 46 were less than 10 tons each, while the average shipment was 15.85 tons.

About 572 tons netted the owner less than $5 per ton. The Wamukah Mining Co. pays cash for ore. The furnace is not working nearly at capacity. The Company is about to help the development of this and nearby counties. According to *The Ouray Herald*, one great drawback to progress in this direction is that every mineralized area is staked, and if not patented is held by assessment work only.

TELLER COUNTY (CRIPPLE CREEK)

In its *Press Bulletin* No. 201, the U. S. Geological Survey has the following to say regarding the Cresson discovery:

"Whenever any discovery is made in science or technology there appears to be an irrepressible tendency on the part of those who supply news to the general public to state that the new information 'upsets all previous theories.' This stock phrase may generally be put down as an exaggeration, and in many of its applications is wholly untrue. The phrase is in particular favor with the reporter of mining news, to whom the discovery of a new orebody in a district is the signal for immediately consigning all previous geologic opinion concerning that district to the scrap heap. This predilection is well illustrated by the press accounts of the wonderfully rich body of ore recently found in the Cresson mine at Cripple Creek at a depth of 1200 ft. Most of these accounts state that the find 'upsets all previous theories of the U. S. Geological Survey.' Of course, no such disaster has occurred. Anyone who will take the trouble to read for himself the brief chapter of 16 pages in the Survey's report on the Cripple Creek district, published in 1906, which sums up the geologists' conclusions on the origin of the ores and the future of the district, can easily ascertain that the statements there made have been fully confirmed by the mining developments of the last eight years. Moreover, the occasional discovery of rich orebodies, even below a depth of 1000 ft., was distinctly predicted. It is well known that all scientific conclusions are subject to modification in the light of new data, for science is always progressive, but it should be better known that press reports of the total destruction of scientific conclusions by a new fact are likely to be 'grossly exaggerated.'"

On No. 5 level of the Midget mine on Gold hill, lessees are opening a lode 12 ft. wide, assaying up to $100 per ton. The superintendent of the property, W. Allen, states that the mine's output is 30 cars per month from 10 sets of lessees.—Lessees on No. 2 level of the El Paso mine have deposited in a local bank five sacks of ore worth $1000 per sack.——Cripple Creek people, headed by A. P. Mackey, have acquired the Red Lion claims in the southern part of the Goldfield, Nevada, district.

IDAHO

The Idaho State Mining Association closed its annual convention at Boise on January 20. The officers elected for the ensuing year are J. F. McCarty, of Wallace, president; A. E. Carlson, of Boise, vice-president; and Ravenal MacBeth, of Mackay, secretary. The directors are H. L. Day, Wallace; Irvin E. Rockwell, Bellevue; Frank E. Johnesse and A. G. Vaneman, Boise. Seven sets of resolutions were passed by the Association. One resolution strongly indorses the Deadwood Creek highway bill, providing for the building of a star route into the Deadwood mining district. Another highly commends the Public Utilities Commission for its recent decision in permitting legitimate competition in the power business in Idaho. A third recommends passage of a bill providing for an extension of water-power resources of Idaho, incorporation with the federal government, and an appropriation of $20,000 for carrying on the work. A workmen's compensation law along safe and sane lines was recommended.

SHOSHONE COUNTY (COEUR D'ALENE)

Mining and business conditions in the Coeur d'Alene are reported to be quite satisfactory, when everything is considered. However some of the operators in the district do not think so as a number of the largest properties are closed and prices for lead and silver are low, copper unsatisfactory, zinc being the only metal showing strength. At the same time it is conceded that this part of Idaho is probably as prosperous as the rest of the country.

The Hecla company paid 1c. per share, or $10,000, on January 20, making $3,200,000 to date. Over 70 tons of zinc concentrate per day is being produced by the magnetic separators at the Success. A flotation plant may be added. Seven feet of zinc ore has been cut in the Terrible-Edith mine above Murray. Carbonate and galena have been cut in the Square Deal claims. The Castle Rock on Placer creek has sent its first shipment, amounting to 40 tons of 15% copper ore, to Tacoma. The mine is developing well.——The Antimony Mining Co., on Pine creek, has opened 10 in. of 55% ore for a length of 60 ft. ——Shipments are to be made.

MICHIGAN

HOUGHTON COUNTY (THE COPPER COUNTRY)

'Rock' from the conglomerate lode of the Calumet & Hecla is now producing about 100,000 tons per month, and the amygdaloid lode between 80,000 and 87,000 tons. Eighteen months ago the respective tonnages were 140,000 to 150,000 tons, and 100,000 tons.

The daily output of 'rock' from the district is about 32,400 tons, some of the shipments being as follows: Calumet & Hecla, 8500; Quincy, 4200; Copper Range, 5000; Mohawk, 2500; Allouez, 1600; Isle Royale, 2100; Kearsarge, 3000; Wolverine, 1700; Centennial, 700; Mass Consolidated, 700; Superior, 750; Victoria, 250; and Osceola, 650 tons.

MONTANA

SILVERBOW COUNTY

Repairs at the Leonard mine are finished, and the shaft is in operation again, after being closed for 21 days. Ore hoisting was to have been suspended at the Gagnon and Original mines, but will continue for a time. The Anaconda company is making numerous improvements at its Mountain View shaft. Save the copper being sent to the Great Falls refinery, the Company will start in February to send from 1000 to 1500 tons of metal to Tacoma, and load there on steamers for New Jersey, by way of the Panama canal.

NEVADA

CHURCHILL COUNTY

The Nevada Hills company's output in December was 6200 tons of $6.666 ore, of which 75.5c. per ton was profit, the total being $4683. Mine development amounted to 402 ft. The resources of the Company are $256,546, of which $24,703 is silver on hand. Temporary arrangements have been made for the disposal of the silver produced in the future. The annual report will be mailed about February 1.

ESMERALDA COUNTY

Cripple Creek people, headed by A. P. Mackey, have acquired the Red Lion claims in the south part of Goldfield, adjoining the Yellow Tiger mine. The manager of this property, C. D. Wilkinson, will superintend work for the Colorado investors. ——A 100-hp. motor is on its way to the Yellow Tiger to drive the 8-drill compressor.——Stoping has been started in the Jumbo Extension; and January profits are estimated at $60,000. ——An incline rise above 250 ft. in the Florence has cut 4 ft. of $40 to $70 ore.

HUMBOLDT COUNTY

The Rochester mining district is described by Frank C. Schrader in *Bulletin* 580-M of the U. S. Geological Survey. The work covers 48 pages and is accompanied by a geological map and several small illustrations. The writer visited the district in May 1913, and a preliminary review was published

in the following month. The area is about 25 square miles in the Humboldt range, which is 75 miles long, and has Star peak as its highest point, 10,000 ft. above sea-level. The report discusses the history, geology, rocks, lodes, minerals found (53), mining development, and gravels of several areas in the district. Regarding the future of the district, Mr. Schrader wrote as follows: "From the deep-seated character of the deposits and their close association with the major geologic structures, which are shown to have been impressed upon the rocks of the region from the tops of the mountains to some distance below the floors of the deepest valleys, the deposits may reasonably be expected to extend to considerable depth. In the sulphide zone, however, they will probably become leaner and more regular in tenor than in the present workings, which are chiefly in the oxidized zone."

LYON COUNTY

Forty-five men are employed on construction of the Nevada-Douglas leaching plant, and good progress is being made.——The Smith Valley mine is being examined by G. W. Lloyd. The property is in the hands of a receiver, but has good prospects.

NYE COUNTY

Twelve hundred tons of material is to be hauled to the Round Mountain company's placer property by the Wittenberg Warehouse & Transfer Co. The pipe-line will be 8½ miles long. It is hoped to have water on the claims in May.

Tonopah produced 10,395 tons of ore worth $213,070 during the third week of January. Some December returns are as follows: Belmont, 14,865 tons yielding 3422 oz. gold, 315,452 oz. silver, and a profit of $117,604; Extension, profit of $66,485, and $456,712 in 1914; and Jim Butler, profit of $13,339, and $279,290 in 1914.——The drift at 1230 ft. in the Merger has passed through the fault and cut the orebody.——Ore taken

WEST END MILL, TONOPAH.

out during development of the Montana is to be treated at the West End mill. The Montana company is to prospect its northern portion through the Umatilla company's ground.——On account of the illness of Curtis H. Lindsay the Jim Butler-West End suit argument has been postponed to the middle of February.

NEW MEXICO

GRANT COUNTY

(Special Correspondence.)—At Lordsburg, the 85 Mining Co. is shipping 325 tons of ore per day to the Calumet & Arizona smelter at Douglas, and the smelter at El Paso, but the former has issued a notice that it is not in the market for any more ore.

Lordsburg, January 22.

SIERRA COUNTY

The newly organized Las Animas Peak Gold Mines Co. has started shaft sinking at the El Oro claim. Machine-drills are to be used later on. C. J. Hutchinson is manager.

OREGON

BAKER COUNTY

The new stamp-mill of the Golden Gate mine at Greenhorn is now working. There is about 42 in. of snow at the mine.

JEFFERSON COUNTY (RECENTLY PART OF CROOK COUNTY)

Locations of gravel claims covering 20 by 40 miles, along the Deschutes and Crooked rivers and Squaw creek were filed on January 13, with the clerk of this new county. Extravagant reports are being circulated about the discovery, such as $1.50 to $15 gold, $2.40 platinum, and $2 silver per ton, also 24½ milligrams of radium per pound of ore, tin and nickel. One person interested stated that "the discovery means $100,000,000 per year to the business of Portland, and untold wealth and a development of this state never dreamed of."

JOSEPHINE COUNTY

Practically all the indebtedness of the Almeda Mining Co., of Grants Pass, has been paid, according to the president, T. S. Burley. Within 90 days it was hoped to have the concern adequately managed. It is proposed to erect a 200-ton concentrating plant in addition to the existing 100-ton smelter. With the power-line to be constructed, the improvements will cost $75,000. Iowa, Ohio, and Portland, Oregon, people are interested, the president residing in the latter city.

UTAH

BEAVER COUNTY

At 150 ft. the Beaver-Butte Mining Co. has opened the vein for 20 ft. in width, assaying from $5 to $10 per ton.

JUAB COUNTY

The south end of the Van stope of the Iron Blossom is yielding on an average of 500 oz. silver per ton.——A drift is now developing ore cut by the diamond-drill in the Chief Consolidated, which promises to be a good shoot.——Development in the Grand Central is confined to the 1100-ft. level, which is being extended to cut the vein opened at 900 and 1000 ft.——Zinc ore in the Gold Chain winze below 1200 ft. is mixed with the gold-silver ore, and is a nuisance, as it means a penalty on shipments. The 700 and 1000-ft. levels are producing copper, and lead-silver-gold ore.

SALT LAKE COUNTY

The annual meeting of the Salt Lake Stock & Mining Exchange was held on January 23. The president, R. J. Evans, spoke on the Exchange keeping open throughout the war, when others in the world were closed. There are 68 members at present, the limit being 75. The building is worth over $70,000. Transactions during 19 years totaled 230,000,000 shares worth $120,000,000.

SUMMIT COUNTY

The Daly-Judge company is shipping over 500 tons of 45% zinc concentrate per month. The ore comes from between the 500 and 1200-ft. levels, where a large tonnage is ready for stoping.

WASHINGTON

FERRY COUNTY

(Special Correspondence.)—A new electric hoist has been installed at the Surprise mine by the Western Union Mines Co.——At 250 ft. in the Knob Hill, 4 ft. of $27 ore has been cut. The metal is mainly gold. S. H. Richardson is the new manager.——The Superior Court of the county has issued an order in favor of the Quilp Mining Co. for a survey and examination of the formerly disputed ground surrendered to the Company by the Republic Mines Corporation, and now under bond and lease to the Western Union company.——M. H. Joseph has been elected city treasurer of Republic.

Republic, January 16.

CANADA

British Columbia

The Old Sport property in the Quatsino district on Vancouver Island, comprising 27 patented claims and embracing approximately 2000 acres of ground, has been sold by W. E. Cullen, of Spokane, and W. M. Bacon, of Butte, Montana, to the Stewart Mining Co., of Kellogg, Idaho. Thirty miners from the Stewart passed through Spokane recently en route to Quatsino. Another party of 20 is scheduled to leave Kellogg soon. The Old Sport group comprises a part of the original holdings in the Quatsino region of Conrad Wolfe and Sidney Rosenhaupt and other Spokane men, and was taken over from them several months ago by Mr. Cullen and Mr. Bacon under lease and bond for $500,000, of which $20,000 already has been paid, and the remainder has been provided for. The consideration involved in the last deal cannot be learned.

Yukon

The wood-hauling season is in full swing, to Dawson and

POSITION OF THE CANADIAN KLONDYKE CO.'S NO. 2 DREDGE AT THE END OF 1914, WHICH SANK DURING OCTOBER.

the various creeks in the Klondike, and many teams will deliver thousands of cords up to the end of March.

PHILIPPINE ISLANDS

(Special Correspondence.)—The Philippine government is badly in need of more revenue, having had a loss of about ₱7,000,000 in 18 months, and has under consideration an output tax on gold produced in the Islands. The mining interests are strenuously opposing this, but it is expected that a tax of 1.5% on the year's yield will be imposed. The property tax may be removed, but this is doubtful. The proposal of the former collector of customs was a 4 or 5% tax. The present time is not suitable for increased burdens, and the legality of the measure is doubtful. As the government has stopped railroad and other work, labor is plentiful.

The Colombo Mining Co., in charge of H. B. McCoy, is mining 150 tons of ore per day. After paying two 5% dividends in 1914, the surplus was ₱400,000. This is invested in New York 6% bonds.——The Syndicate at Masbate is also doing well. A 6 by 16-ft. tube-mill has been added to the mill. ——At the Benguet Consolidated, mill machinery is going to the mine, but the hydro-electric equipment has not been received. C. M. Eye is manager.

Manila, December 13.

According to the U. S. Geological Survey, the gold output of the territory steadily increased and was over $1,000,000 in 1914. The Philippine Dredges Co. produced 1080 oz. gold in December. One boat was under repair

PERSONAL

Arthur W. Burgess is now at 539 Holbrook building, San Francisco.

R. B. Lamb is examining gold properties at Grass Valley, California.

L. F. S. Holland has returned to Los Angeles from Searchlight, Nevada, where he has been making an examination.

Howland Bancroft has just returned to Denver from an extended trip into British Columbia and is now engaged in professional work in Colorado.

A. J. M. Ross, of the engineering department of the Homestake Mining Co., South Dakota, is in charge of the Company's exhibit at the Panama-Pacific Exposition.

Bayliss C. Clark has recently returned to California from Antioquia, Colombia, where for the past year he has been examining placer properties for Breitung & Company.

Bruce C. Yates has been appointed assistant superintendent of the Homestake Mining Co., South Dakota. He has been with that Company for twenty years, being chief engineer for some time.

William H. Kritzer has returned to San Francisco from El Dorado, California, where he has been supervising alterations in the three unit 150-ton Lane slow-speed Chilean mill plant of the Shan Tsz Gold Mines Company.

Robinson T. White, formerly of Butte, Montana; Salt Lake City; Bayonne, New Jersey; and Coram, California, was manager of the Caucasus Copper Co.'s mines, Russia, when the Turkish troops attacked that place, but eventually escaped to Batum.

Thomas Walters has resigned as superintendent of the Jones & Laughlin Ore Co., the Inter-State Iron Co., and the Leetonia Mining Co., after a period of service of over 30 years. He will continue to act as superintendent of the Pittsburgh & Lake Angeline Iron Co., and the Lake Angeline mine until the two small bodies of ore still remaining in the mine have been worked out.

Schools and Societies

The Idaho Mining Association met at Boise on January 19 to elect officers and discuss matters of interest.

The Montana section of the A. I. M. E. meets at Butte on February 5 for election of officers and reading and discussion of papers by Theodore Simons and Paul Billingsley.

The A. I. M. E. will hold its New York meeting on February 15 to 17. About 50 papers will be presented, besides other discussions. Some of the Society's by-laws will be submitted for amendment.

The Australasian Institute of Mining Engineers will meet in the west coast mining districts of Tasmania in the latter part of February or early in March. The Mt. Bischoff tin, Mt. Lyell copper, and other mines and works will be visited.

The Canadian Mining Institute's Cobalt branch met on January 15. The topic of discussion, led by R. B. Watson, of the Nipissing mine, was on the essential features of a report on a mining subject. The president of the Institute, G. G. S. Lindsay, attended.

Inauguration of the Engineering Foundation was held in the Engineering Society building, New York, on January 27. The Engineering Foundation, inaugurated by the United Engineering Society, is the name given to a fund to be "devoted to the advancement of the engineering arts and sciences in all their branches, to the greatest good of the engineering profession and to the benefit of mankind."

THE MARKET PLACE

Weekly Summary of Prices of Shares and Metals

Metal Prices

San Francisco, January 28.

Antimony	18 —18¾
Electrolytic copper	14½—14¾
Pig lead	3.95— 4.90
Quicksilver (flask)	$52.50
Spelter	7½— 7¾
Tin	34½—36
Zinc dust, 100-kg. zinc-lined cases	10

EASTERN METAL MARKET

Our weekly telegram giving metal prices in New York has been delayed in transmission.

SILVER

Below are given the average New York quotations in cents per ounce, of fine silver.

Date.		Average week ending	
Jan. 21	48.87	Dec. 16	49.83
" 22	48.50	" 23	48.66
" 23	48.75	" 30	48.65
" 24 Sunday		Jan. 6	48.65
" 25	48.87	" 13	48 98
" 26	48.87	" 20	48.98
" 27	48.75	" 27	48.77

Monthly averages.

	1913.	1914.		1913.	1914.
Jan.	63.01	57.58	July	58 70	54.90

Apr.	59.26	58 52	Oct.	60.88	51.12
May	60.21	58.21	Nov.	58.76	49.12
June	59.03	56.43	Dec.	57.73	49.27

The past week's market was steady. The 'Persia' took $85,451, or 180,000 oz., from San Francisco to the Orient on January 23. Diamonds from India and the Continent have enabled London dealers to dispose of some metal. Samuel Montagu & Co.'s 'Annual Bullion Letter' is now at hand, and should be secured by silver producers; also Pixley & Abell's chart showing silver business for 82 years.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

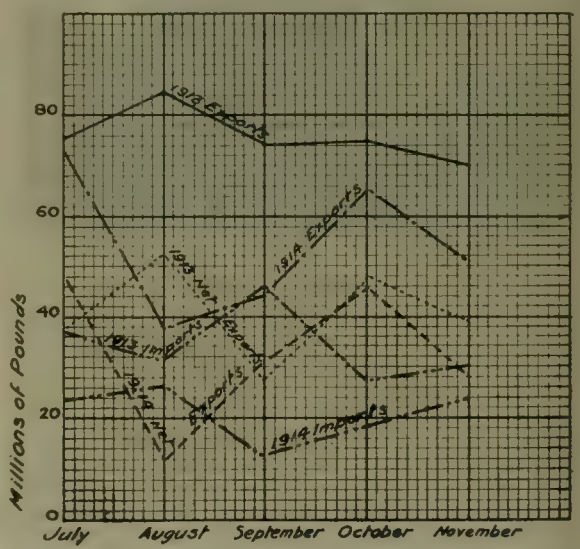
Copper is firm at 14.25 to 14.50c. per pound.

The Calumet & Hecla has advanced its selling price to 14.75c., which the National Conduit & Cable Co. states is too high, as domestic stocks are large. Exports last week totaled 23,057,055 lb., against 7,836,759 lb. in the previous week. The American Smelting & Refining Co. is selling electro to Russia. December output of Utah Copper was 6,795,567 lb., and Nevada Consolidated 2,651,658 pounds.



Copper exports, imports, and net exports for the United States, July to November, inclusive, 1913 and 1914. Compiled from reports of the Department of Commerce.

LEAD

Lead is quoted in cents per pound or dollars per hundred pounds, New York delivery.

Date.		Average week ending	
Jan. 14	3.70	Dec. 9	3.80

TIN

Tin is steady in New York at 35.45 to 36.25c. per pound. There has been a good rise in prices in London.

MINING DECISIONS

FORFEITURE OF CLAIM—PLEADING AND PROOF

Although it is the general rule that the forfeiture of a mining claim for non-performance of assessment work must be specially pleaded, just as any other forfeiture must be pleaded, a sufficient proof and finding of the facts constituting a forfeiture will cure the defective pleading. The opinion of a laborer as to the value of the work is proper evidence, even though he be not qualified as an expert.

Cache Creek Mining Co. *v.* Brabenberg (Alaska), 217 Federal, 240. October 13, 1914.

MINING LEASE—INVALID SURRENDER

An implied surrender of a mining lease does not arise from mere notice of the lessee's intention to give up the lease, and pay no further rentals and his failure to make such payments. There must be an actual surrender of the lease by one having authority so to do. If the lessee is a corporation it must be authorized by corporate action. The president of the corporation has no inherent power to surrender. Right of lessor to recover rentals sustained.

Laing *v.* Price (West Virginia), 83 Southeastern, 497. October 29, 1914.

EMINENT DOMAIN—PRIVATE USE

A mining company sought to condemn a right-of-way through the property of an adjoining company for a tunnel for transportation of ore. Both ends of the tunnel were in perpendicular shafts on the private property of the plaintiff, and said tunnel could therefore not be used by mine owners generally except by plaintiff's consent. The Arizona constitution provides (sec. 17, art. 2): "Private property shall not be taken for private use except for private ways of necessity, and for drains, flumes, or ditches, on or across the lands of others for mining, agricultural, domestic, or sanitary purposes." Held, that the tunnel right-of-way sought in this proceeding did not come within the designation of "private way of necessity" in the absence of express legislative determination to that effect.

Inspiration Consolidation Copper Co. *v.* New Keystone Copper Co. (Arizona), 144 Pacific, 277. November 25, 1914.

This interesting case has been discussed in the *Press*, and the dispute has been settled by the plaintiff buying the defendant's property.

OIL LOCATIONS—VALIDITY

Several persons interested in a location of oil land conveyed their rights to one of their number for convenience in handling the land for their benefit. He neglected to do the assessment work for one year, and being of the opinion that the original locators could not re-locate after such failure, he was not guilty of fraud in procuring a re-location by other relatives for the benefit of the original parties. In February 1909, the claim was conveyed to the Obispo Oil Co., which thereafter expended considerable sums in drilling, without making a discovery, however. The location was then conveyed to the Pacific Midway Oil Co., which, after an expenditure of $24,000, discovered oil and proceeded with continuous development. Held, that as no showing of fraud was made and a discovery proved prior to the passage of the act of June 25, 1910, that act was inoperative as to the vested rights in these claims. The executive withdrawal order of September 1909 has already been held invalid.

United States v. McCutcheon (California), 217 Federal, 650. September 1, 1914.

BOOK REVIEWS

HEATON'S ANNUAL, 1915. Commercial handbook of Canada and boards of trade register. Edited by Ernest Heaton, J. Beverley Robinson, and W. J. Dobson. P. 514. Index. Heaton's Agency, 32 Church street, Toronto. Price, $1, and 12c. for postage.

Like the 'World' and 'Whitaker's' almanacs, in the United States and England, Heaton's is almost indispensable as a reference work on the Dominion of Canada. The work covers everything of interest going on in that country. Fourteen pages are devoted to the mining industry. The 'Where to Find It' pages are an economic bibliography of all government reports. The promptness with which the book is issued makes it valuable for the past and current years.

THE CANADIAN MINING MANUAL. Edited by Reginald E. Hore, of the *Canadian Mining Journal*. P. 273. Illustrated. Mines Publishing Co., Toronto. For sale by the *Mining Press*. Price, $2.

Originally this annual was founded by the late B. T. A. Bell, and eventually passed to the present publishers, who now issue the first number under their direction. The work might be termed the 'Skinner' of Canada, as it gives details of nearly all the operating companies of the Dominion, covering them in from three lines to as much as eight pages, according to their importance. Coal mining in several provinces is discussed by writers, and short chapters devoted to the important minerals and metals recovered. Numerous illustrations are included, the lithographic work being excellent. It is a fitting handbook for an industry which produced $144,031,047 in 1913.

UNIVERSAL SAFETY STANDARDS. By Carl M. Hansen. P. 312. Ill., index. Universal Safety Standards Publishing Co., New York, 1914. For sale by the *Mining Press*. Price, $3.

This valuable work is a reference book of rules, drawings, tables, formulae, data, and suggestions for use of architects, engineers, superintendents, foremen, inspectors, mechanics, and students, compiled under the direction of and approved by the Workmen's Compensation Service Bureau, New York. It is a handbook of concrete examples of safeguarding, and rules for practice in machine shop and foundries, and is the first one of a series of books to be issued by this Bureau. The author strikes the keynote of industrial safety when he lays down the principles of safeguarding in such a way as to make one realize that he is fully capable of handling this immense problem. Compensation laws have made indemnity for accidents compulsory. This indemnity is one of the large items in the cost of production. To reduce this cost and effect a saving in operation, accident prevention is one of the most prolific fields. Employers and others interested in safety, need authoritative information on the methods of assuring safety, which will meet the requirements of the ruling of their insurance companies. The book describes and specifies conditions and machines, and safe means and measures for guarding these conditions and machines. With each specification is shown a detailed drawing of what the specification means, all of which is the application of the principle of safeguarding. This arrangement makes everything absolutely clear even to the machine operator. Interesting examples are the treatment of stairways, steam engine devices, and grinding-wheel protection. The book is profusely illustrated, there being 206 pages of line-cuts showing how to protect employees from dangerous equipment, the important features being colored in green. Generally it should be in the hands of employers and employees, who will find in it much food for thought and practical value.

COMPANY REPORTS

DE BEERS CONSOLIDATED MINES, LTD.

This is a great diamond company of Kimberly, South Africa, and the report is for the year ended June 30, 1914. Results were as follows:

	1914.	1913.
Diamonds sold and increase in stocks	£5,123,335	£6,297,782
Balance from previous year	513,521	807,388
Other income	228,770	143,068
Total revenue	£5,865,626	£7,248,238
Cost of mining	2,205,985	2,080,622
Depreciation	253,700	706,035
African taxes	262,125	426,465
Interest and sinking fund	234,900	235,932
Profit	2,672,836	3,799,183
Deferred dividends	1,250,000	1,500,000
Bonus	.....	250,000
To reserve fund	51,253	140,060
Unsold diamonds	919,320	595,601
Balance to current year	447,864	513,521

The Vorspold mine was bought for £394,023. The stock of 'blue' ground on the floors is 11,331,022 loads (1600 lb. each), compared with 10,803,054 loads. The value of this ground varied from $3.06 to $4.24 per load, and the value of the diamonds from $11.60 to $20.16 per carat. Owing to the war the ordinary working of the mines has been suspended.

IRON BLOSSOM CONSOLIDATED MINING COMPANY

This Company operates in the Tintic district, Juab county, Utah, and the report covers the year ended December 1, 1914. Details of the output are as follows:

Ore mined, dry tons	40,480
Average metal content:	
Gold, ounces	0.1454
Silver, ounces	28.11
Lead, per cent	9.78
Copper, per cent	0.238
Value per ton	$22.23
Gross value	$899,943
Cost of mining, etc.	242,232
Cost of freight, sampling, and smelting	351,561
Profit	306,150
Dividends	400,000

Cash at the end of the year was $127,034, and bills receivable, $215,000. Development in the mine totaled 8755 ft., making 46,789 ft. to date, and was more in the way of drifts and cross-cuts to and through the orebodies in order that mining might be done more economically. The east fissure has proved to be an extensive orebody. At 1900 ft. the drift is out 2500 ft. from No. 1 shaft. This is for exploration of certain country. There is a large tonnage of first and second-class ore on hand. Mining costs, $5.36 per ton, increased owing to the necessity of filling old stopes, whereby 950 ft. of cross-cuts and 1369 ft. of rises were driven in waste to secure the required filling material.

SULPHIDE CORPORATION, LTD.

This is one of the most important companies operating at Broken Hill, New South Wales. Its operations cover the Central mine and concentrating mill at Broken Hill, smelter at Cockle Creek near Newcastle on the east coast, and works in England. The mill treated 209,074 tons of ore averaging 12.1 oz. silver, 14.4% lead, and 16.9% zinc, yielding 34,317 tons of lead concentrate and 64,798 tons of zinc concentrate. The extraction was 89.1% silver, 93% lead, and 93.9% zinc. The net profit for the year was £165,227, against £280,947 in the previous period. Dividends amounted to £200,000, but on account of the war further distributions are inadvisable.

The report contains a great deal of interesting discussion on the increased cost of mining and development, capital expenditure at Broken Hill, income tax, slime treatment, the Mond gas plant which is producing by-products, superphosphate production (10,027 tons), cost of realizing lead concentrate, German bombardment of the east coast of England where the Central Zinc works are situated, and Germany's influence in the sale of lead and zinc concentrates. Of 131,316 tons of the latter produced during the past two years, 19,633 tons was treated in England and 116,296 tons was sold to Beer, Sondheimer & Co., of Frankfurt. The war stopped further shipments to Germany, which was a severe setback to the Company.

Like the previous volume, this one is full of interesting and valuable matter pertaining to the mines of the Marquette range, which produced 2,463,973 tons of iron ore in 1914. Abstracts will be made for the *Press* from the articles published.

New Machines and Devices

Large Jaw Crushers

In crushing rock or ore the first breaking of the solid material is done by drilling and blasting, the broken material is then taken to crushers for the next step in the operations of crushing. In studying the economics of the operations the question arises whether it is cheaper to break the material in small pieces in blasting or to break it in large pieces and continue the reduction mechanically with crushers. In any individual instance other factors enter and complicate the problem, but speaking generally, the decision hinges on the relative cost of drilling and blasting, and that of mechanically breaking in large crushers. In order to use the powder efficiently in blasting, it is necessary to place it to the best advantage, which involves a good deal of drilling, and drilling is expensive. Even where most of the rock is broken in fairly small pieces, there will be some large ones which must be re-drilled or bulldozed to reduce them to a size which will enter the jaws of the crushers, and this special work is expensive. In open-cut work, especially, the total cost can often be lowered by providing crushers large enough to take the largest pieces. The importance of this consideration has been appreciated by the Traylor Engineering & Manufacturing Co., of Allentown, Pennsylvania, which has developed large primary crushers. The Company has furnished to the H. S. Kerbaugh Co. at Valhalla, New York, a mammoth jaw crusher with a jaw opening 60 by 84 in., which eliminates to a great extent the bulldozing and plugging or mud-capping of rock, as any rock which can be picked up by a six-yard steam-shovel can be fed into the jaw opening. The Kerbaugh crusher is used for crushing rock for the building of the Kensico dam, which is a part of the $200,000,000 water-supply system of the city of New York. This crusher had a large part in establishing a world's record by the Kerbaugh company when it placed in the dam, in 25 working days, 8-hour shifts, 83,000 yd. of concrete.

Another crusher of the same size has been built for the H. W. Johns-Manville Co., to be used in crushing the asbestos rock at the mines of this Company in Canada. Even these crushers were not large enough, so the Traylor company is now building for the Rockland Lake Trap Rock Co. a crusher with jaw opening 66 by 86 in. to be used for crushing trap rock. This machine will be installed just outside of New York City, and will weigh over 520,000 pounds.

A notable feature in the manufacture of these large crushers is the fact that practically the whole machine is constructed of cast steel throughout, thoroughly annealed, so as to eliminate all internal strains. This machine is, according to information furnished by the Traylor company, approximately 26 ft. long, 18 ft. high, and 20 ft. wide; the crushing plates are made of manganese steel, and also the cheek plates and toggle seats, giving these wearing parts the longest possible life. The pitman is of extra heavy construction, made of cast steel, of the box section type, and fitted with internal ribs and with a removable cap so as to facilitate handling. The pitman is also fitted with removable bushings, babbitted and water-cooled. The use of bushing for this part greatly facilitates the rebabbitting of the eccentric or pitman whenever necessary and eliminates the necessity of shutting down the crusher for two or three days, which would be the case if the babbitt was poured in place in the pitman. Large crushers of this kind usually have a set of spare bushings, thoroughly babbitted, which allows of the quick rebabbitting of this essential part of the machine. The bearings on the side frames are also fitted with removable bushings, water cooled, and babbitted. This also allows of the quick rebabbitting of the bearings, if by any chance the operator should allow the babbitt to burn out. Under normal operating conditions, however, the babbitt need not be touched in a whole year's operations. In fact, in the large crushers which are running, the babbitt is not touched except when the plant is shut down for two weeks in the winter time for overhauling. It is not necessary, however, to do this, as it has been found at the end of the year that the babbitt was in as good condition as when the crusher started.

The water cooling features on these large crushers must not be overlooked, since it is thereby possible to run the crushers continuously without any possible chance of the bearings

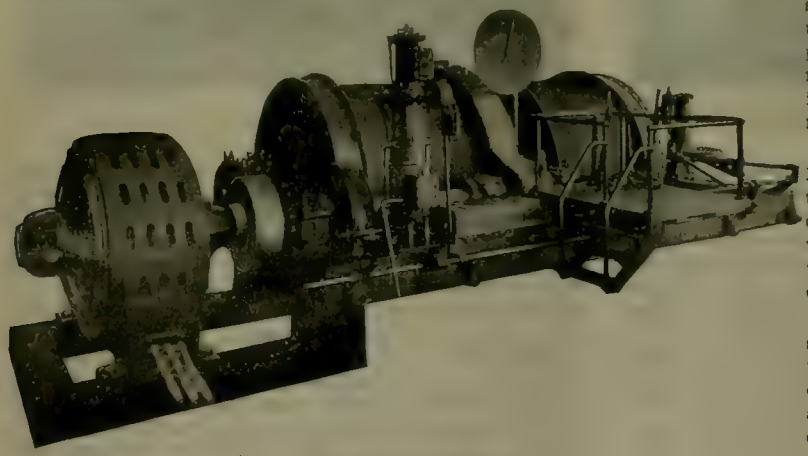
TWO GIANT JAW CRUSHERS BUILT BY THE TRAYLOR ENGINEERING & MANUFACTURING COMPANY.

heating, and the lubricating expense is greatly reduced; only about one-third of the lubricant necessary under ordinary conditions is used with water-cooled bearings. This water-cooling device has worked so satisfactorily on these large crushers that the Traylor company has adopted this design for all of its jaw crushers. In addition to the saving in quarrying cost, owing to the large openings on these large crushers, the machines have such an enormous capacity that the cost of crushing is also reduced. The crusher for the Rockland Lake Trap Rock Co. will have a capacity of 400 tons per hour, crushing down to about 10-in. ring, and will use from 180 to 240-hp. in crushing; estimating from actual operating conditions of the other large crushers in use.

While the Kerbaugh crusher at Valhalla was stopped through some oversight, ten tons of rock was dumped into the machine. It was absolutely prohibitive to dig out all of this, so the power was turned on and there was enough momentum in the crusher and also power in the motor to start the crusher and clean itself, without having to dig out a single piece of stone. At another time the crusher was fed with ten tons of rock, and as the car was dumped the power went off, but there was enough momentum in the fly-wheels to operate the crusher until all of the rock dumped into the hopper had been crushed. This is an important feature to operators who purchase their power, as it is impossible for them to know when the power will go off a line. With a gyratory crusher, for instance, it would be absolutely impossible to crush a load, if by any chance the crusher was full and the power went off. The box section type of crusher, shown in the cut, was built for the Kerbaugh company, while the ribbed section was built for the H. W. Johns-Manville Co. The Johns-Manville crusher has a large band wheel, 16 ft. diameter, and will receive the belt power direct from an electric motor. The Rockland Lake crusher will be driven direct from a countershaft and the main pulley will be 12 ft. diameter and 44 in. wide.

The Largest Induction Hoist

The largest induction motor, shaft hoist equipment in America was placed in operation in November 1914, at Lansford, Pennsylvania. The driving motor is rated at 750-hp., 300 r.p.m., three-phase, 25 cycle, and drives through a single reduction gear. Positive control of the hoisting speed is secured by means of an improved type of liquid rheostat and high-tension air-brake contractors, the motor circuit being 2300 volts. This hoist serves a 600-ft. vertical shaft hoisting 11,500 lb. per trip at the rate of 90 trips per hour, with a maximum rope speed of approximately 1600 ft. per minute.



LARGE INDUCTION HOIST.

The liquid rheostat was developed primarily for mine hoist service, and insures safe operation at quick reversal. It employs two sets of fixed electrodes at different elevations. One set is widely spaced, while the other set has large electrode areas and has small spacing in order to obtain a very low final slip. The two sets of electrodes are connected in parallel after the electrolyte has reached a certain level corresponding to a predetermined decrease in rotor voltage. All parts of the rheostat itself are stationary, thus insuring absolute reliability. The electrolyte level is varied through the operation of a movable weir and a small motor driven pump. The electrical equipment was supplied for this hoist by the General Electric Co. of Schenectady, New York.

Commercial Paragraphs

CHALMERS & WILLIAMS, Chicago Heights, Illinois, is installing two 6 by 14-ft. patent adjustable quick-discharge tube-mills at the Hunter mill in Shoshone county, Idaho.

The WEBSTER MANUFACTURING CO., Tiffin, Ohio, in a recent leaflet illustrates the 'car pullers' manufactured by this Company. These are made in various forms and adapted to a wide variety of purposes.

WOOD DRILL WORKS, Paterson, New Jersey, make drills from the 8-in. 'giant' weighing 2600 lb. to the little 2-in. 'baby' of only 83 lb. A recent folder illustrates the 2600-lb. 'giant' manufactured by this Company.

The LAGONDA MANUFACTURING CO., Springfield, Ohio, has issued a bulletin entitled 'Lagonda Boiler Tube Cleaners' in which are illustrated and described the new type of cleaners manufactured by this Company.

ARTHUR D. LITTLE CO., Boston, Mass., in a recent number of *The Little Journal*, publishes a short article entitled 'Raw Materials and the War,' the purpose of the article being to show the effect of the European struggle upon the American market.

The DODGE SALES & ENGINEERING CO., Mishawaka, Indiana, has been organized and incorporated to distribute all of the products of the Dodge company. Duncan J. Campbell, for several years general sales manager for the old Company, goes to the new corporation as vice-president and general manager, and C. R. Trowbridge continues in charge of advertising and sales promotion.

DAVIS INSTRUMENT MANUFACTURING CO., Baltimore, Maryland, has for distribution leaflets descriptive of the sighting compasses, pocket mining hygrometers, water gages, and psychrometers manufactured by this Company. Prices are quoted on these instruments.

C. L. BERGER & SONS, Boston, Massachusetts, is distributing a folder calling attention to the large stock of transits and other surveying instruments which are always kept on hand at the Boston headquarters. Visiting engineers are invited to call and inspet the products of the Company.

The MESTA MACHINE CO., Pittsburgh, Pennsylvania, is the manufacturer of what is claimed to be a highly efficient and reliable condensing device. The Helander barometric condenser is simple in construction and erection, and is built entirely of cast iron, and hence is unaffected by acid or oily water. There are no rivet holes to become leaky, and the condenser is capable of a large overload without impairing the efficiency.

ARTICLES

LOOKING FORWARD 208

Sixty-five per cent of the copper produced in the United States is exported to Europe, and of the exports Germany absorbed about 30%. When the war started, copper was declared contraband by England, consequently shipments to Germany fell off greatly, resulting in copper mines of the United States curtailing production to about 50% capacity. Exports of copper to neutral countries in Europe have gradually increased of late, but England declares its right to detain cargoes of copper, unless they are specifically bound for known firms, or will not be allowed to pass into German hands from the neutral countries. The subject is of considerable importance.

LAKE SUPERIOR COPPER MINING: PRESENT AND FUTURE—II.

By Thomas T. Read 209

This is the second article of the series on this important district, the first appearing in the *Press* of December 5, 1914. In the present one, Mr. Read discusses mining methods from all points of view, beginning with a short résumé of the history of timbering and what conditions have altered the systems. The general scheme of mining consists of sinking incline shafts in the lodes, starting levels 100 ft. apart, and beginning stoping as near the shafts as is possible with safety. The Michigan mines are worked to a great depth, resulting in increased costs for many reasons. Hand tramming is a feature underground, on account of the drifts following the ore, making anything but straight runs. A great amount of ground is kept open, this being a peculiarity resulting from the price of copper. One-man drills are coming into general use in the world's mines, and their work in the Copper Country is described. Filling worked-out stopes is a problem everywhere, the Michigan mines being no exception to this rule, but the sand from the stamp-mills will probably solve the question. Mr. Read's article concludes with cost data of mining at the principal properties.

THE MEKEEL TUNNEL.

By Charles S. Shaunessy 216

A short account of driving a tunnel in connection with the water supply of the city of New York.

ORGANIZATION AT THE TREADWELL CYANIDE PLANT 217

Co-operation between employers and employees is desirable in any industry, and a better understanding is growing in the mining districts of the United States and in those of many other countries. The Alaska Treadwell Gold Mining Co. has furthered this idea in many ways with satisfactory results.

LATENT POSSIBILITIES AMONG CALIFORNIA MINERAL RESOURCES.

By E. S. Boalich 218

Mineral output of California is valued at approximately $100,000,000 per year, of which 50% is from petroleum and 20% from gold. The state contains deposits of most of the industrial minerals, but generally speaking there has been no incentive to develop them and produce any large quantity. Now that the war has cut off supplies of certain of them, such as antimony, asbestos, chrome ore, magnesite, and manganese ore, these should be worked.

A WEIR IN BURMA 219

The illustration accompanying this note shows native construction of a weir in jungle country, for determining stream flow preliminary to installing a water-wheel.

GERMAN IRON AND STEEL INDUSTRY 219

The output of iron and steel dropped considerably early in the war, but is now increasing.

THE PATO AND NECHI PLACER PROPERTIES, COLOMBIA.

By W. A. Prichard 220

These dredging claims of the Oroville Dredging Co. have been the subject of a great deal of interest to mining men. After a year's work, Mr. Prichard reports as to the amount of gravel available for the dredges. The Pato is estimated to contain 22,419,490 cu. yd. worth $7,092,100, and the Nechi 6,855,900 cu. yd., valued at $4,926,600.

BURRO MOUNTAIN PORPHYRY COPPER DEVELOPMENTS.

By Faris V. Bush 222

The Burro Mountain mine at Tyrone, New Mexico, is the newest porphyry deposit being developed and gradually brought to the producing stage.

GOLD MINING IN EASTERN ASIA 224

These notes describe methods used by the Celestials in various regions, and show that they are not wanting in skill.

THE RAND'S LARGEST CENTRAL POWER-STATION.

By V. Pickles 225

The Rand is a mining centre of enormous production, and great plants are necessary for this output. Mr. Pickles describes the largest of the many power-plants, the air-compressing system being of importance.

STOCK LIST

A WAREHOUSE OF HOISTING ENGINES
ONE HALF OF OUR YARDS
A ROW OF STEAM ENGINES
A WAREHOUSE OF HOISTS AND ENGINES
HOISTING ENGINES AND COMPRESSORS
A LINE OF SHOP TOOLS
CENTRIFUGAL PUMPS AND SHOP MACHINERY
A FLOOR OF GENERAL SUPPLIES

Immediate Shipment Second-Hand Material

The following pages list Machinery we actually have in Denver stock ready for immediate shipment.

These views give you a visual idea of a part of our plant.

We handle in and out of Denver over 600 carloads annually of used machinery.

Our yards have over a mile of tracks, nineteen warehouses, sheds and shops.

The value of our stock at new price of machinery is over $3,000,000.

Every plant dismantled in the West has been purchased by us. We dismantled and shipped to Denver, in 1914, 136 plants of mining, milling, and smelting machinery.

Seventy-five percent of the machinery listed on the following pages has been in actual use less than 90 days.

You can probably secure the very article you are figuring on new and save one-half the purchase price.

Write us your requirements. If you do not see what is wanted in the following lists, write us. We are continually buying plants and it is possible we have exactly what you want. Write us today.

The Morse Bros. Machinery & Supply Co.

DENVER, COLO.

MORSE BROS. DENVER STOCK LIST

Specifications and Prices

Specifications, giving all details as to size and conditions will be sent on request. Photographs of any article will also be sent. It is our desire to give you the most complete information in regard to any article you wish, so that you may have the complete data before you. More than one-half our business is mail orders and is purchased on our statement of condition and is guaranteed in every way.

We have new and different goods arriving daily, and if you do not see what is wanted in the following lists write us about it.

CRUSHERS

4—Keedy Ore Sizers.

STEEL TANKS

72" dia. x 60" High Steel Tanks, 3/16" Steel; Cap. 1050 gallons.
72" dia. x 36" High Steel Tanks, 3/16" Lead Lined; Cap. 630 gallons.
9' 6"x6' 6" High Steel Tanks, ⅛", 5200 gallons
16'x10' High Steel Tanks, 3/16", 15,000 gallons.
5—Sand Tanks, 8,000 gallons, with slat bottoms; sides No. 10 Ga., bottom 8 Ga., steel.
1—Stock Tank, 9,000 gallons.
2—Sump Tanks, 8,000 gallons
4—16x12 Solution Tanks.
3—38x 5 Leaching Tanks, 2 discharge gates, filter cloths, cocoa mats, bored false bottom.
6—17x6 Sump Tanks, 2½" Angle iron at top.
2—15x8 Water Tanks.
4—Conical Tanks, 10' dia., 7' to cone; cone 4' 8" opening.

MISCELLANEOUS

No. 1 "Vezin" Double Sampler.
20 Assay Balances.
1 Variable Speed Regulator.
7 Challenge Ore Feeders.
7 Challenge Ore Feeders.
12x24 Pierce Amalgamator.
1 Pierce Amalgamator, 32x24.
Perrin Filter Press, 24 plate bot. disch.
Lot of Mill Side Dump Cars
7 Belt Elevators complete.
2 Link Belt Elevators complete.
1 Split Sampler.
2 Belt Driven Samplers.
1—4x4 Standard Mine Cage.
Lot of 6", 3" and 2" Pipe
Lot of 8, 12, 16, 24, 35 and 50-lb. Relaying Rail.
Lot of one cubic foot Zinc Boxes.
6 Dble Zinc Box, 18 comp. in each box, 24x24, 20" to top of screen; Trays and Rods.

ROASTERS AND DRYERS

9—18-foot 6-hearth McDougal Roasters. Main shaft and Rabble arms water cooled. Each machine driven by clutch pulley from main shaft. In excellent condition in every respect.
Revolving Ore Dryer, 60"x18'
1—D. E. Wks. Multitubular Ore Dryer.
1—90-ton Cummer Ore Dryer 11x28'6".
3—Revolving Ore Dryers, 5x22'6".
2—Davis Revolving Ore Dryers.
1—90' Edwards Duplex Roasting Furnaces
2—Howell-White Revolving Roasters, 36x 5' x7½".
60x8 Edwards Roasting Furnace, self contained steel girder frame.
5—No. 139 Prinz & Rau Perfection Dust Collectors.

BLAST FURNACES

1—48x186 Allis-Chalmers Blast Furnace.
2—39x168 Allis-Chalmers Blast Furnaces
These furnaces are all in fair condition. The jackets are more or less warped. The large furnace has been re-set and has never been in use. The bottoms are of cast iron resting on jack screws. Complete blast and down-take pipes and fittings.

REVERBERATORY FURNACES

1—17x55'. 1—17x42' 1—17x52'
The iron work of all these furnaces is as good as new, is I beam buckstays, 1½" binder rods, charging hoppers, doors, grates, etc

FURNACE AND CONVERTER EQUIPMENT

9 Elliptical Slag Cars, 66x51x57, gauge 48, wheels 24.
4 Steel Bowl Slag Cars, Elliptical, 72x54x 41 gauge, 30".
2 Larry Cars, 57x78", bot. disc., electrical driven, 250 v.d.c.
4 Matte Ladles or Pouring Spoons, cast steel.
5 Mould Cars, 92" long, 42" gauge.
60 Hand Slag Pots, 28" dia. bowl, 25" wheels.
2 Cast Iron Turntables, 42" gauge.
44 Reverberatory Matte Pans, 52x18x9.
56 Reverberatory Matte Bells, 7x10 base.
1 Ingersoll Tamping Machine for Converters.
2 Steel Scrap Boats.
11', 16' and 16' Matte Settling Wells
50' Cast Iron Trough for furnaces.
25 tons of smelter bars and tools.

RADIAL DRILL PRESSES

1—Alfred Box & Co., belt drive, drills to center of 60" circle.

ROLLS FOR SHEET IRON

1 set 36"x3½" Sheet Iron Rolls, Bertsch & Co.
1 set 50"x5" Doty Geared Rolls, hand power.

HAMMERS

1—Flint & Lomax Trip Hammer.

PLANERS

1—22" Putnam Iron Planer, Bed 19"x5'.
1—24 Ames Mfg Co. Screw Drive, Bed 19"x5'.
1—E. C. Dickey Pulley Key Seater.

PIPE MACHINES

1—No. 46 Forbes Pipe Machine for power and hand.
1—No. 7 Jarecki Pipe Machine. Cuts ¼" to 2" pipe.
1—Curtis & Curtis Pipe Machine. Capacity 2½" to 6", with countershaft.
1—Curtis & Curtis Pipe Machine. Capacity 2½" to 6", direct connected to 1 H.P. D. C. 1280 RPM. Westinghouse motor.
1—N. O. Nelson Pipe Cutting Machine. Capacity ½" to 2", with countershaft.

BOLT MACHINE

1—No 2 Putnam Bolt Cutter, ⅜" to 1½", with taps and dies and countershaft.
1—Reliance Bolt Cutter, complete with taps and dies and countershaft.
1—No. 1 General Electric Oil Tempering Bath with basket for same, including "M" Panel pipe supports, rheostat, switchboard and thermometer.
1—¼ to 1½ Wiley & Russell Bolt Cutter.
1—Wells Bros Nut Tapper.
1—Brown Bolt Machine, ⅜ to 1½.

DRILL SHARPENERS

1—No. 1 Sinclair drill sharpener and bull-dozer with extra dies.
1—No 1 Leyner drill sharpener and bolt header with dollies and dies.

MISCELLANEOUS

1¼ Yard Vulcan Steam Shovel on R. R. trucks.
No. 500 Victor Steam Shovel on R. R. trucks.
1 Yard Thew Automatic Revolving Shovel, traction wheels.
Model 10 Marion Steam Shovel on R. R. trucks.
New Erg Grader, complete.
17 CF Municipal Cube Mixer with boiler and engine.
No. 5 Smith Mixer on skids.
Sack Cole, Concrete Mixer on skids with gasoline engine
1 Steam Derrick, mast 16x12, 4x6 double steam engine, direct connected to derrick windlass.
2 Hand Power Derricks, 10x10 mast.
2 Marble Gang Stone Saws.
1 Marble Planer.

WATER TUBE BOILERS

3—300 H. P. Rust Vertical Boilers.
2—200 H. P. Babcock & Wilcox.
1—200 H. P. Moraine Water Tube.
1—150 H. P. Heine Water Tube.
2—250 H. P. Cahall Vertical.
1—125 H. P. Sterling Water Tube.

HORIZONTAL TUBULAR

Diameter inches, first; length in feet, second; number of tubes; third; size of flues, fourth.
15—150 H. P., 78x18, High Pressure Butt strapped, quadruple riveted, Otis steel, 86, 4" tubes.
1—125 H. P., 72x16, 70, 4".
1—100 H. P., 66x16, 72, 4"
1—100 H. P., 60x18, 82, 3".

40 H. P. 44x14, 46, 3"
35 H. P. 44x12, 38, 3"
20 H. P. 36x10, 28, 3"

BOILERS—LOCOMOTIVE

250 H. P. Marine, Dia. 10', length 13', 137-3½"
100 H. P. Holthoff Internal Furnace.
100 H. P. Penn. Ret. Tubular Portable, 82-3" and 46-4" flues.
80 H. P. Erie Economic, Dia. 54", 78-3" and 42 flues.
60 H. P. Erie Economic.
60 H. P. Locomotive Type.
30 H. P. Erie Economic.
30 H. P. Locomotive, Dia. 36" 30-3 flues.

The following are new locomotive type, mounted on skids. These were bought at receivers' sale and will be sold at less than the manufacturer's cost.

60 H. P., 40" Dia., 64x38x50 fire box, 18 3" tubes.
50 H. P., 40" Dia., 60x34x44 fire box, 42 3" tubes.
40 H. P., 40" Dia., 60x34x14 fire box, 42 3" tubes.
25 H. P., 36" Dia., 52x30x40 fire box, 34 3" tubes.
20 H. P., 34" Dia., 52x28x38 fire box, 30 3" tubes.

VERTICAL

40 H. P., 48x96, 136—2" submerged flue.
35 H. P., 42x 9½, 84—2" full length tubes
35 H. P., 42x 9½, 109—2" full length tubes
30 H. P., 42x 9, 84—2" full length tubes
30 H. P., 42x 8½, 109—2" full length tubes
30 H. P., 42x 9, 85—2" submerged tubes
30 H. P., 42x 9, 82—2" full length tubes
30 H. P., 42x 9, 85—2" submerged tubes
30 H. P., 42x 9, 85—2" submerged tubes
25 H. P., 42x 8, 85—2" submerged tubes
25 H. P., 42x 8, 85—2" submerged tubes
25 H. P., 42x 8, 85—2" submerged tubes
25 H. P., 35x 9, 72—2" full length tubes
25 H. P., 42x 7½, 109 —2" full length tubes
20 H. P., 36x 8, 77—2" full length tubes
18 H P., 36x 7, 61—2" full length tubes
18 H. P., 36x 7, 61—2" full length tubes
12 H. P., 30x 7, 48—2" full length tubes
5 H. P., 24x 5, 31—2" full length tubes

The following are NEW and will be sold at manufacturer's cost.

1—25 H. P., 42x7½, 96—2"
3—20 H. P., 36x8, 72—2".
3—18 H. P., 36x7, 72—2".
2—15 H. P., 36x6, 72—2".
1—12 H. P., 30x7, 48—2".
5—10 H. P., 30x6, 48—2".
4— 8 H. P., 30x5, 48—2".
3— 4 H. P., 24x4, 28—2".

FEED WATER HEATERS

40 H. P. Webster.
50 H. P. Frost Tubular.
70 H. P. Standard. 100 H. P. Webster.
100 H. P. Wainwright
150 H. P. Standard Enclosed.
250 H. P. Standard Enclosed.

CORLISS ENGINES

1—20x42 "Allis" L. H., Girder frame.
1—16x42 "Fraser-Chalmers" R. H. Girder frame.
1—16x42 Filer & Stowell R. H., Heavy Duty frame.
1—16x36 Jackson L. H. Corliss.
1—14x42 "Fraser-Chalmers" L. H. Girder frame.
1—12x30 Allis-Chalmers R. H., Heavy Duty frame.
1—12x24 "Philadelphia" Corliss R. H., Girder frame.

COMPOUND ENGINES

320 H. P. 30x16x27 "Fitchburg" Tandem.
100 H. P. 9x12x20 "Atlas" Tandem.

AUTOMATIC ENGINES

1—150 H. P., Armington-Sims, 15x15, Automatic.
1—150 H. P., 16x24, Atlas side crank.
1—125 H. P., 15x16, Ball.
1—120 H. P., 13x12, Ball.
1—120 H. P., 13x15, Ball.
1—120 H. P., 13x12, Ideal.
1—100 H. P., 14x20, Atlas side crank.
1—100 H. P., 12x13, Ball.
1— 75 H. P., 12x12, Buffalo.
1 — 70 H. P., 11x13, Ames.
1 — 60 H. P., 12x20, Watertown.
1 — 50 H. P., 12x12, Hendey & Meyers
1 — 50 H. P., 10x12, Buffalo.
1 — 45 H. P., 10x12, Ball.
1 — 40 H. P., 9½x10, Armington-Sims
1 — 25 H. P., 7x10, Atlas.
1 — 25 H. P., 7x10, Armington-Sims.
1 — 25 H. P., 8x10, Hendey & Meyers
1 — 15 H. P., Rice Automatic

SLIDE VALVE ENGINES

80 H. P., 14x20, Atlas.
80 H. P., 14x18, Woodbury.
80 H. P., 14x18, Bay State.
80 H. P., 13x12, Ideal, center crank.
70 H. P., 14x18, Houston & Gamble.
65 H. P., 12x18, Woodbury.
60 H. P., 10x17, Hendey & Meyers.
60 H. P., 13x16, Chandler & Taylor slide crank.
50 H. P., 11x15, D. E. Works.
50 H. P., 13x16, Chandler & Taylor.
50 H. P., 12x12, Oil Well Link Motion.
50 H. P., 11x15, Hendey & Meyers slide crank.
50 H. P., 12x16, Star.
45 H. P., 11x16, Atlas (2).
40 H. P., 11x14, Jackson.
40 H. P., 11x14, Chandler & Taylor.
40 H. P., 10x16, Star center crank.
40 H. P., 10x15, W. B. & F. side crank.
35 H. P., 9x18, Horiz. center crank
35 H. P., 10x12, Card & Weber.
30 H. P., 9x12, Atlas.
25 H. P., 8x12, Hendey & Meyers (2).
20 H. P., 8x10, Denver Eng. Works
15 H. P., 7x10, Nagle.
15 H. P., 7x10, Atlas
15 H. P., 7x10, Mansfield.
12 H. P., 6x 8, Nagle, center crank.
5 H. P., 4x 6, Murray Iron Works.

VERTICAL ENGINES

20 H. P., 9 x9, Nagle.
15 H. P., 8 x9, Nagle.
15 H. P., 6½x7, Oil City Automatic.
15 H. P., 8 x9, New York Safety.
12 H. P., 7 x8, Vertical.
10 H. P., 7 x7, Nagle.
8 H. P., 5½x7, Climax.
7 H. P., 6 x6, Nagle.
5 H. P., 6 x7, O. & S.
4 H. P., 4 x4, Nagle.
4 H. P., 4 x4, Climax.
4 H. P., 4 x6, N. Y. Safety.
3 H. P., 3½x5, Nagle.

The following new vertical engines can be secured at less than the cost of manufacture.

15 H. P., 7½x10, Dutton.
10 H. P., 7½x 8, Dutton.
8 H. P., 6 x 7½, Dutton.
6 H. P., 5 x 7½, Dutton.

GASOLINE ENGINES

30 H. P. Weber. 25 H. P. Alamo, new.
25 H. P. Fairbanks, Morse & Co., horizontal.
1212 H. P. Fairbanks, Morse & Co., vertical.
8 H. P. Novo, horizontal.
6 H. P. Royal, horizontal.
5 H. P. Otto, horizontal.
4½ H. P. Royal, horizontal.
1½ H. P. Ingeco, horizontal.
1½ H. P. Royal, horizontal.
1 H. P. Jack Junior.

OIL ENGINES

85 H. P. De La Vergne, Type H. A.
80 H. P. Fairbanks-Morse, Type N., 180 R.P.M., 8x16.
3—17 H. P. Bull Dog Duplex, new, a bargain.

DIRECT CONNECTED UNITS

200 Kilowatt Chuse Automatic, 19x20. Direct connected to 2 Comp. "Bullock," 125 v. and 800 amperes, 200 R.P.M.

3 McIntosh-Seymour 18x40x36 Cross Compound 1000 H. P. Engines, direct connected to.

3 G. E. AC Generators, 600 K.W., 3 ph., 30 cyc., 52 amp., 6600 volts.

20 Kilowatt Direct Current, 250 volts, direct connected to 8x8 Racine Automatic Vertical Engine

ALTERNATING CURRENT MOTORS

1—300 H. P. Westinghouse, 3 ph., 60 cyc., 450 v., Synchronous Motor, 150 R.P.M., pulley 32x30, with control board. Complete in every detail.
1—250 K.W. Westinghouse Synchronous Motor, 3 ph., 60 cyc, 180 v., 150 R.P.M.
1—150 H. P. Westinghouse Motor, 3 ph., 60 cyc., 400 v., 580 R.P.M.
150 H. P., 3 ph., 60 cyc., 440 v., General Electric, 600 R.P.M.
100 H. P., 3 ph., 60 cyc., 440 v., General Electric, 720 R.P.M.
1—100 H. P. Gen. Elect., Form L, 3 ph. 60 cyc., 440 v., 125 amp., 600 R.P.M.
40 H. P., 3 ph., 60 cyc., 220 v., Westinghouse, 840 R.P.M.
50 H. P., 3 ph., 60 cyc., 440 v., General Electric, 600 R.P.M.
30 H. P., 3 ph., 60 cyc., 440 v., Bullock, 850 R.P.M.
25 H. P., 3 ph., 60 cyc., 440 v., General Electric, 900 R.P.M.
20 H. P., 3 ph., 60 cyc., 440 v., Bullock, 850 R.P.M.
20 H. P., 3 ph., 60 cyc., 440 v., Bullock, 1130 R.P.M.
10 H. P. Single Phase Wagner, 1750 R.P.M.
1—10 H. P., F. M. & C., 3 ph., 60 cyc., 220 v., 1200 R.P.M. Motor
½ H. P., 3 ph., 60 cyc., 440 v., General Electric, 1200 R.P.M.

DIRECT CURRENT MOTORS

1—50 H. P., Ft. Wayne, 3 ph., 60 cyc., 440 v., 600 R.P.M., Motor
10 H. P., 500 v., direct current, Northern, 625 R.P.M.
35 H. P., 250 v., Bullock, 610 R.P.M.
35 H. P., Crocker-Wheeler, 600 R.P.M., 230 v.
25 H. P., 250 v., Bullock, 900 R.P.M.
26 H. P., Crocker-Wheeler, 230 v.
20 H. P., 250 v., Bullock, 650 R.P.M.
20 H. P., 250 v., Bullock, 650 R.P.M.
1—20 H. P., Westinghouse, type S, 500 v., 1040 R.P.M., 34 amp., Motor
1—20 H. P., Northern Electric Co., 220 v., 80 amp., 725 R.P.M., Motor
1—20 H. P., Westinghouse, 500 v., 1050 R.P.M.
1—20 H. P., Northern Electric Co., 220 v., 35 amp., 725 R.P.M., Motor.
15 H. P., 110 v., Electron, 1200 R.P.M.
1—15 H. P., Westinghouse, 220 v., 1120 R.P.M.
15 H. P., Crocker-Wheeler, 800 R.P.M., 230 v.
13 H. P., Crocker-Wheeler, 230 v.
10 H. P., Gen'l Elec., 500 v., 800 R.P.M.
1—10 H. P., Milwaukee, 500 v., 1275 R.P.M.
1—7½ H. P., Crocker-Wheeler, type CCM, 875 R.P.M., 230 v., 28.5 amp. Motor.
1—7½ H. P., Crocker-Wheeler, type CCM, 875 R.P.M., 230 v., Motor.
5 H. P., Crocker-Wheeler, 230 v., 1300 R.P.M
5 H. P., Crocker-Wheeler, 250 v., 1229 R.P.M.
3 H. P., 500 v., Gen'l Elec., 1800 R.P.M
1—¼ H. P., G. E. Type C 2, 500 v., 2000 R.P.M.

DIRECT CURRENT GENERATORS

10 K.W. Crocker-Wheeler, 250 v., 1085 R.P.M.
26 K.W. Edison, 125 v., 1300 R.P.M.
7½ K.W. Kentucky, 220 v., 1050 R.P.M.
4½ K.W., 125 v., Westinghouse.
Jenney Elect. Co. Generator, 5 v., 60 amp., 2200 R.P.M.
3 K.W. Edison, 250 v.
3 K.W., Crocker-Wheeler, 125 v., 1220 R.P.M.
1½ K.W., Crocker-Wheeler, 125 v., 2075 R.P.M.

ELECTRICAL EQUIPMENT

200 K.W. Generator Set, Allis-Chalmers Bullock Type Motor A. C., H. P. 300, Volts 440, Amp. 354, R.P.M. 865, 60 Cycle. Generator, direct current, volts, no load, 240; full load 250; amperes 800; R.P.M. 865. Perfect condition.

3—100 K.W., each Oil Cooled Transformers, 44,000 to 440 volts, 60 cycle. Allis-Chalmers.

3—100 K.W., each Water Cooled Transformers, 44,000 to 440 volts, 60 cycle. Westinghouse.

1 Complete Set, 44,000 volts, Lightning Arrester.

1—5-panel Switch Board, marble, complete

1—2-panel Switch Board, marble, complete.

2—75 K.W. Pittsburg Transformers, high tension, 4600 to 10,000 volts.

3—100 K.W., each Water Cooled Transformers, 440 to 10,000 volts.

WATER WHEELS

36" Leffell Standard Vertical.
30" Samson Vertical.
24" Climax Water Motor.
18" Smith Globe Case Turbine.
17" Triumph Case Turbine.
15½" Leffel Globe Case Turbine.

STEAM PUMPS—Mine Pumps

18 and 28 and 42x10x35 Knowles Triple Expansion Duplex with 12x20x18 Vacuum Pump, capacity 1200 gal., 1000 lift.
18x34x9¼x36 Snow Duplex Compound Condenser Pump, 12x18x16, 800 gal., 100 feet lift.
26 and 15x8x24 Knowles Duplex Compound Pot Valve Pattern with independent jet condenser.
24 and 14x7x24 Knowles Duplex Compound with independent jet condenser. Solid cylinder pattern.
20x8x12 "Knowles" Duplex O. P. Plunger.
18x8x12 "Knowles" Duplex O. P. Plunger.
16x7x12 "Knowles" Duplex O. P. Plunger.

MORSE BROS. DENVER STOCK LIST

11x7x14 Knowles Duplex, outside end packed, solid cylinder pattern.
11x6x12 Knowles Single. 147 g.p.m.
12x7x12 "Knowles" Duplex O. P. Plunger.
10x6x12 Knowles Duplex. 204 g.p.m.
10x6x10 Snow Duplex. 188-205 g.p.m.
10x6x12 Knowles Duplex. 204 g.p.m.
2—10x5x12 Knowles Pressure Pumps.

SINKING PUMPS

No. 12 Cameron Sinker, 18x9x16.
1 No 1, No. 11 "Cameron" Sinker, 16x8x16.
2 No 9B "Cameron" Sinker, 14x7x13.
1 No. 9 "Cameron" Sinker, 12x7x13.
1 No. 7 "Cameron" Sinker, 10x5x13.
1 No. 5 "Cameron" Sinker, 7x3½x12.
Prospector's Sinker, 6x3x7.
Snow Duplex Sinker, 10x5x12
Snow Duplex Sinker, 7x3½x10.
Deane Sinker, 12x6x16

GENERAL SERVICE PUMPS

2—12x18½x12x10 "Deane" Compound Duplex Inside Plunger. Capacity 880 gal per minute.
16x10½x12 "Worthington" Duplex. 600 gal. per minute.
14x8½x12 "Snow" Duplex. 470 gal. per minute.
2—16x12x10 Laidlaw-Dunn-Gordon Piston Duplex, brass fitted.
14x10x12 Fairbanks-Morse Duplex. 1,020 gal. per minute.
16x9x12 "Knowles" Duplex.
16x8x20 Hooker Single.
14x7x24 No. 5 Cameron Special.
12x7x10 "Worthington" Duplex. 600 gal per minute.
12x6x12 "Snow" Duplex. 465 gal. per min.
10x6x10 "Worthington" Duplex. 220 gal. per min.
10x6x10 Davidson Boiler Feed.
8x5x12 Knowles Duplex.
8x8x12 Fairbanks-Morse Duplex.
8x12x18 Snow Single.
7x4½x8 Snow Duplex; Piston Pattern.
6x8½x10 "Snow" Simplex Tank. 260 gal. per min.
6x8½x12 "Snow" Simplex.
2 No. 6 Deane Single.
6x4x6 National Duplex.
6¼x4x6 Buffalo Duplex, outside center packed.
5¼x3½x5 Knowles Duplex.
5¼x3½x5 Buffalo Duplex, outside center packed.
5¼x3½x5 Worthington, outside end packed.
4½x2¾x4 Deane Duplex.
5¾x5x10 New Era Duplex.
Lot of Boiler Feed Pumps of Worthington, Blake & Knowles, Snow and other makes.

TRIPLEX, DUPLEX AND SINGLE POWER PUMPS

3—13x12 New Aldrich Triplex, 1000 g. p. m. against 250" head.
13x12 Aldrich Single Acting. Capacity, 900 g. p. m.
9x10 Deming Triplex, 75 lbs. pressure.
8x10 Gould. Fig. 1062 for open wells, cylinders below. Capacity, 244 g. p. m.
8x8 Gould Triplex, 43 lbs. pressure.
4½x8 Gould. Fig. 997. 44 g. p. m. 600 lbs. pressure, new.
8x8 Deming Single Acting. 287 g. p. m., 150 lbs. pressure.
5x8 Gould Triplex, 43 lbs. pressure.
5x8 Gould Triplex. 91 g. p. m. Fig. 924. 130 lbs.
4x6 Gould Triplex. 48 g. p. m. 130 lbs.
3x4 Dean Duplex. 100 lbs. 18 g. p. m.
3—4x6 Fairbanks-Morse Duplex Power Pumps, 78 g. p. m.
1—5x5 Goulds Pyramid Pumps, 40 g. p. m.
1—No. 11 Lucas Low Pressure, 40 g. p. m.
1—5x5 F., M. & Co. Bulldozer, 35 g. p. m.
1—5x5 Goulds Pyramid Pump, 34 g. p. m.
1—Goulds Deep Well Pump Head, 20" stroke.
1—National Deep Well Pump Head, 36" stroke.

CENTRIFUGALS

8" Morris Horiz. Mang. Lined Sand Pump.
7" Traylor, Horizontal Centrifugal.
6" Traylor Vertical Centrifugal.
6" Hodge Horizontal Centrifugal.
6" Louisville Horiz. Centrifugal.
5" Boggs Clark Horiz. Centrifugal.
5" Traylor Horiz. Centrifugal.
4" Kingsford Horiz. Centrifugal.
4" Fountain Vertical Centrifugal.
3" Buffalo Horizontal Centrifugal.
3" Boogs & Clark Horizontal Centrifugal.
2½" Byron Jackson Horiz. Centrifugal with extended base for motor.
2" Fountain Vertical Centrifugal
1½" Fountain Horizontal Centrifugal.

STEAM ACTUATED COMPRESSORS

1925 cu. ft. Norwalk compound air and steam compressor, 28 and 17½x18 and 30x30.
1314 C. F. Laidlaw Dunn Gordon, 18 and 30x26 and 16x24, compound steam and air.
1250 C. F. Rand Imperial Type 10, compound air and steam; 24 and 14x24 and 13x16.
1160 C. F. Norwalk Corliss Valve, steam, 14 and 26, air 22 and 13½, stroke 24".
800' Rand Imperial, Type 10, Compound Steam and Air, 20 and 12x19 and 11x16.
647 C. F. "Leyner" Straight Line, 16x18 and 11x22. Simple Steam Compound Air. (Have two of these.)
656 C. F. "Rand" Straight Line, Class "A"—18x18¼x24.
584 C. F. "Rand" Imperial, Type 10—9x16 and 9x12, Duplex Steam Compound Air.
558 C. F. "Norwalk"—14x16 and 9½x16 simple steam compound air.
558 C. F. "Norwalk" Comp. Air, simple steam, 16 and 9½x14x16.
498 C. F. "Ingersoll," Clas "A"—14x16¾x18, simple steam and air.
481.7 C. F. Leyner Simple Steam, Compound Air, 11½x16 and 10x18.
439 C. F. "Ingersoll," Class "H3," 11 and 19x18¼x10, compound steam, compound air.
417 C. F. No. 9 McKernan, 14x14x18.
282 C. F. Norwalk, High Altitude, 10x12 and 6¾x12.
274' Leyner, Simple Steam, Compound Air, 10½x12 and 7¼x14.
220 C. F. American 10x12x12. Straight Line, Type "A."
195 C. F. "Norwalk"—10x10x6¾x10, simple steam compound air
180 C. F. "Leyner"—10½x10x6¾x14, simple steam compound air.
153 C. F. American—8x10x12, simple steam, simple air.
80 C. F. Laidlow, Class "GB"—8x8x8, simple steam and air
31 C. F. Ingersoll, 6x6x6.

BELT DRIVEN AND DIRECT CONNECTED COMPRESSORS

1007' Ingersoll-Rand, Class J2—24¼ and 14¼x11.
530 C. F. Blaisdell Comp. Air, 18x12x12 enclosed frame.
1—30 Drill "Ingersoll-Sargent," 22x41x48, 100 lbs. pressure.
481.7 C. F. Leyner Straight Line Side Crank, 16 and 10x18. (We have two of these.)
247 Rand Imperial Type 10, 12x7½x10.
235 C. F. Leyner, 12x12.
154 C. F. Leyner, 10x10.
117 C. F. Franklin, 10x8.
48 C. F. 6x6 Curtis Automatic, 2 cyl., single acting.
34½ C. F. Clayton Single Open Frame, Climax, 6x6.

POSITIVE BLOWERS

1—No. X Garden City Positive Blower.
1—No. 3 Root "New Acme" Blower.
1—No. ¾ Wilbraham Blower.
1—No. ½ W. Baker Blower Co. Blower.
1—No. 4 Bakers Rotary Blower.
1—No. 4½ Baker Positive.
1—No. 5 Bakers Rotary Blower.
1—Piqua Positive Blower. Capacity 85 cu. ft. per rev.
1—100 cu. ft. Connersville.
1— 55 cu. ft. Roots.

VOLUME BLOWERS

1—No. 000 Champion, outlet 4¼".
1—No. 1 Buffalo, outlet 4⅞".
1—No. 2 Buffalo, outlet 6".
1—No. 4 Buffalo, outlet 9".

HOISTING ENGINES

18x36 Davis First Motion Double-conical Drums, for 1⅛-inch rope. Steam operated clutch and brakes.
16x30 Allis First Motion.
14x20 Ottumwa Link Motion Double Drum, wood-lagged.
22x36 Danville First Motion Double Drum Hoisting Engine, drums 7', post brakes.
10x30 First Motion Bolthoff Hoist, load 1000 lbs., 600'.
12¾x15 "Lidgerwood," Style 225 Single Drum, Link Motion Band. Clutch capacity, 6,500 lbs. at 450 feet.
12x16 Vulcan Geared, load 6500 lbs. Hoisting speed 575 ft. per min. 120 H.P.
12x12 Double Friction, Double Engine.
10x12 Friction Hoist.
10x14 Vulcan Geared.
8x10 Davis Geared, 8x12 Webster Geared.
6x8 H. & B. Combination Friction and Geared.
6x8 Vulcan Geared, 20 HP., load 2000 lbs. 350 ft. per min.
6x8 F. M. & Co. Friction, Cap. 2000 lbs., 20 HP., 300 ft. per min.
6x8 Vulcan Friction Hoist, Cap. 2000 lbs., 20 HP., 300 ft. per min.
6x8 Mine & Smelter Friction, 2000 lbs., 20 HP., 300 ft. per min.
6x8 Friction Hoist.
6x8 National Single Cyl. Eng., double friction Hoist, Cap. 1500 lbs. (Have 2 of these.)
5x6 Davis Geared Winze, 1200 lbs., 150 ft. per min.
2—5x7 H. & B. Geared Hoists.
1—Davis Horse Whim.
3—Reynolds Safety Horse Whims.
1—No. 1 Walker Mfg. Co. Hand Winch, cap. 10,500 lbs.
1—No. 2 Montgomery Hand Winch, load 5250 lbs.

CONTRACTORS' HOISTS

8¾x10 Lidgerwood Engine and Boiler, link motion drum, 32x23.
8¾x10 Lidgerwood Three-drum, Tandem Style, No. 2093.
7x10 Lidgerwood Double-drum Engine and Boiler, No. 71.
18 HP., Double Drum Hoist and Boiler. Drums, 12x24 and 10x19.
10 HP., 7x10, Lidgerwood Single Cyl. Friction Drum Engine and Boiler.
6 HP. Combined Boiler and Hoist.
1—Lidgerwood Belted Hoist, drum, 10x19. Capacity 1000 to 1500 lbs.

ELECTRIC HOISTS

15 to 25 HP. Electric Hoist. Motor to suit.
75 HP. Trent Eng. & Machy. Co. Electric Hoist.
Lidgerwood Double Drum Tandem, Drums 27x27 and 36x27.
Lidgerwood Double Drum Tandem, Drums 14x27.
Lidgerwood Double Drum Tandem, Drums 36x48 and 26x55.
Lidgerwood Triple Drum Tandem, Drums 44x39, 30x50 and 30x50.

GASOLINE HOISTS

34 H.P. Fairbanks-Morse.
15 H.P. "Alamo." 15 H.P. "Witte."
15 H.P. Fairbanks-Morse.
12 H.P. Fairbanks-Morse, vertical.
9 H.P. Fairbanks-Morse, vertical.

ELECTRIC LOCOMOTIVES

Jeffrey Electric Locomotive, 48" gauge, Ty DM Class, 105 volts 250; DB pull 6500 lbs., hand wheel brakes wheels 29", drum controller, trolley in center, extra motors and armature.
General Electric Locomotive, Class LM 103 A, volts, 250, gauge 24", DB pull 1200 lbs., speed 6 miles. Extra armatures and motor.
General Electric Locomotive, 5 ton, Form L, M. 103A, 24" gauge, 1200 lbs. DB pull, speed 6 miles, 500 v., direct current.
3-ton Atlas Storage Battery Locomotive, 24" gauge with 10 H. P. G. E., 220 v., direct current generator.

TRAVELING CRANE

45,000 lbs. Browns Hoisting and Conveying Co. No. 2012, span 40 ft.

GOLD DREDGE

1 Complete 5 C. F. Bucket Gold Dredge, electrically operated with separate 300 K.W. Electric Power Plant. Used three months. Digs 35' below water line. Can be secured at a bargain.
1 Uro & Snyder Gold Dredge, cap. 1000 yds. per 24 hours. Ladder 24'. 70 H. P. Miami boiler engine. Gold saving devices, etc. A good dredge for a small placer.

TRAMWAYS

1 Complete 6150' Leschen Tramway with buckets, terminals, rope, etc.
1 Complete 1800' Jig Back Montgomery Tramway.

MINING companies in Arizona have complained in the past about the heavy taxation levied, and the new mine tax bill passed by the state senate last week will not lessen their complaints.

SUBJECTS bearing on finance and trade of this country were discussed by an influential gathering, including the President and the Secretary of State, at the third annual meeting of the Chamber of Commerce of the United States, in Washington, D. C., on February 3, 4, and 5.

ORES AND METALS produced in Japan are to be displayed in a considerable area of the Palace of Mines and Metallurgy at the Panama-Pacific Exposition. The booths are Oriental in style, being erected by native workers. A large relief map, in colored clay, of the mining regions is to be a prominent feature of the exhibit.

TRADE of the United States during the calendar years 1914 and 1913 was as follows: Exports, $2,114,257,539 and $2,484,018,292; and imports, $1,789,022,426 and $1,792,596,480, respectively. Considering the domestic depression, the continued farce in Mexico, and the war in Europe, the showing should be considered satisfactory.

AMONG the 2686 bills to be discussed by the State Legislature at Sacramento is one dealing with the gold-dredging industry. The measure is essentially similar to that introduced by Senator Kehoe in the session two years ago, and which was the subject of articles in the *Press* at the time. It is proposed to make the dredging companies leave the land in a suitable condition for farming; and also to place the industry under control of the Railroad Commission, which would have the power to grant permits for gold recovery by this means. These continual attacks on dredging, and smelters also, are very annoying to the respective operators, and in most instances unjustified. When the Legislature convenes again in March, we will discuss this matter further.

MINERS' PHTHISIS has been the subject of considerable controversy in Western Australia for many years; and, although attempts have been repeatedly made to make some provision for incapacitated miners, no good result has yet been attained. As a further effort, the state government convened a conference of employers and employees, and it is now hoped that the workers will be wise enough to accept the scheme proposed, which is an honest attempt to provide for sufferers of lung diseases, without crippling the industry by imposing too heavy a burden on the mine owners. In brief, the Mine Workers' Relief Fund will be raised by each employee paying 24 cents per monthly pay, the mine operators and government contributing a similar amount each. It is estimated that the annual total subscribed would be $120,000, from which the sufferers will receive adequate help.

SAFETY-FIRST publications increase in number, and the latest to reach us is *The Ingot*, issued by the General Safety Committee of the Raritan Copper Works, Perth Amboy, New Jersey. There were 599 men employed in the plant in December, and during the month there was a decrease of 46.57 per cent in the accidents compared with the same month of 1913. Previous months showed much greater decreases, and the committee should feel pleased at the results of its efforts. While on the subject of 'safety,' it may be mentioned that probably the highest award bestowed on any workman in the United States was accorded to Mr. Henry Vinton Neal, a mechanic in the shops of the Boston Elevated Railway Company, on January 29, at the dinner of the American Electric Railway Association, when the president of the American Museum of Safety, Mr. Arthur Williams, named the winner of the Anthony N. Brady memorial medal for safety work. In announcing the award to the recipient, Mr. Williams referred to it as "the highest American order of industrial merit."

THE German demand for Florida phosphates has reawakened, but it is difficult to secure cargo space in the present state of shipping. If more ships become available for carrying cotton to Germany, the two can profitably go forward together. Germany has no phosphate supplies of her own, but imports about a million tons each year from the United States, Belgium, Algeria, and Tunis. The last three are now unavailable sources of supplies, and the whole demand turns toward us. But Germany is not dependent on the natural phosphates for a supply of that necessary element in agriculture, as her Thomas blast-furnaces produce over 2,000,000 tons yearly of high-phosphorous slag, which is used as fertilizer. The iron industry in Germany is now on a 50 per cent basis, chiefly for lack of men, so that the supply

from this source will be correspondingly reduced, while the urgent necessity of keeping up the food supply of Germany is likely to cause the demand for phosphate fertilizer to increase rather than decrease.

BARIUM AND STRONTIUM

Low priced materials, which depend almost entirely on transportation costs, have naturally been most affected by the trade dislocations brought about by the war. In the eastern markets barite imported from Germany has set the basis of competition, as it is of excellent quality and can be laid down in New York at a low price. Barite deposits occur in North Carolina, Tennessee, Georgia, and Virginia, and the companies operating in these districts have heretofore found it difficult to meet the German competition; now that German supply is cut off they are in a correspondingly favorable condition. A large part of our domestic production of barite comes from Missouri, and serves the districts of the Middle West in which the imported article is at a disadvantage on account of the freight rates from the eastern seaboard. Barite is used in the manufacture of paints, preparation of rubber, making of wall paper and other paper, coating oilcloth, enameling and glazing industries, and a variety of other uses. Much of that imported has been prepared ready for use, so that the war has not only stimulated production of the crude mineral, but also its preparation for the market.

Strontium is of little importance; everyone knows that its salts are used to make the red fire of fireworks displays, and also the fuses used on railways. It occurs both as the carbonate and sulphate, the former is more desirable, but it is difficult to procure. There are some strontium sulphate deposits in this country, especially near Gila Bend, Arizona, and in San Bernardino county, California. As our previous supplies of strontium salts have chiefly come from Germany, inquiry has naturally turned toward domestic sources of supply; but nothing of much importance seems to have developed as yet. As the total imports of strontium salts in 1913 were less than $3000 there are apparently no fortunes to be made out of it.

THE MINE MULE

Considering his usefulness, it is remarkable how slight a measure of respect the mule enjoys. It has been said of him that he is "without pride of ancestry or hope of posterity," and possibly this may serve to explain his lowly social estate, so that a Missouri mule, selling in the open market for $200 or more, is the butt of ribald jest and the recipient of blows with a cudgel, while the cayuse, dear at $50, is regarded with respect and even affection. Mr. G. E. Wentworth, writing in *The Country Gentleman*, has taken up the case of the mine mule, and presents statistics as to his capabilities. The origin of the mule is ascribed to the shrewd sense of the peasants of southwestern Europe in the Middle Ages, who found that all their best horses were requisitioned by their overlords for service in their wars, and conceived the idea of breeding an animal larger and strong enough for agricultural purposes, but which would not be regarded as sufficiently dignified for service in the cavalry. The astute peasants doubtless, therefore, combined to cast obloquy on the mule, the better to retain his possession, and to this may be ascribed the low repute he enjoys. At any rate, in China, where mules have been bred for many centuries, but feudal conditions have never prevailed, the mule is not regarded with such disesteem.

Many, if not most of the popular beliefs regarding the mule, have no basis in fact, according to investigations made by Mr. Wentworth. The mule does not live and thrive on less food than a horse. Animals of equal weight require equal amounts of food to keep them in condition. With hay at $15.20 per ton and corn at $1.03 and oats at $1.25 per hundredweight, a 1258-pound mule costs 26.68 cents per day to keep on a feed of hay and oats, or 1274-pound mule 23.23 cents on a feed of hay and corn. A 1447-pound horse costs 31.45 cents per day to keep on hay and oats, or a 1535-pound horse 27.21 cents per day on hay and corn. For purposes of comparison, these should be computed to the basis of 1000 pounds weight of animal, on which basis the mule costs 21.2 cents per day and the horse 21.73 cents per day for a feed of hay and oats; or 18.23 cents and 17.71 cents, respectively, on hay and corn. Records of the Missouri Agricultural Experiment Station also support the inference that for animals of equal weight there is no perceptible difference in cost of keep. It is also said that mules live to a great age and can work day and night without being worn out. The rate at which mules are bought in the cotton-growing states of the South indicates that the average working life of the mule is about 5 years. It has been computed that the average working life of a mule underground is 4 years, but this computation was made some time ago, and the better care which mules now receive underground has doubtless lengthened their life. Mr. Wentworth is evidently not an admirer of the mule, for he says: "The average mule is an animal of bad conformation, though of fair size considering its parentage. It is comparatively narrow-chested, of light barrel, high in the leg, and deficient in courage. It is an animal slow of foot, slow of wit, nervous, timid, and distrustful. It is useful in mines where there is very little head room for a draft animal, but in high beds is greatly inferior to the horse." To this the reply might be made that the mule is amply provided with caution and displays no little good judgment in avoiding injury to itself. If it is indeed greatly inferior to the horse underground, then the many companies which have for many years employed mules rather than horses for underground haulage have been following a mistaken policy. We consider the mine mule worthy of his hire, and we offer the privilege of our columns to his defenders.

MOLYBDENUM

One of our subscribers writes to inquire whether there is much demand for molybdenum ores, what the visible supply is, whether the market is constant, and what difficulties are encountered in mining and milling the ores. As this metal is one of those which have been affected by the derangement of trade channels by the war, it will be of some interest to discuss present conditions in some detail.

The principal ore of molybdenum is the sulphide MoS_2, a mineral that so closely resembles graphite that the two are with difficulty distinguished. It occurs in veins in crystalline rocks in many parts of the United States. The Crown Point mine, in Chelan county, Washington, and the Holman mine, at Catherine Hill, Maine, are the best known of the many unsuccessful attempts to develop profitable mines; other deposits occur in Arizona, Utah, Nevada, Oregon, California, Colorado, and Idaho. The difficulty lies in the concentration of the ore, and no one with even a limited knowledge of milling operations will need an explanation why a graphite-like mineral is difficult to concentrate. It has been proposed to apply oil flotation, making use of the tendency of the molybdenite to float, and an excellent recovery can be made in this way, but another difficulty arises. The concentrate must be free from copper, arsenic, bismuth, and tungsten, all of which are highly objectionable impurities. If any of these are present they float along with the molybdenite. Copper is especially likely to be present, and an ingenious way of getting rid of it has been suggested by Mr. James Aston, who proposes to grind the ore in the usual way and then dry it before subjecting it to flotation. During drying, the copper sulphides oxidize on their surface and thereafter will not float, but the molybdenite is unaffected. This promising suggestion has not yet been put into practice, so far as we know. The various attempts to mine molybdenite in this country have all, so far, been unsuccessful, and there was no domestic production in 1913, according to Mr. F. L. Hess. Another molybdate mineral is wulfenite, a molybdate of lead. This is found in many places in New Mexico and Arizona, in the lead regions of Missouri and Wisconsin, at Phoenixville, Pennsylvania, and in Inyo county, California. Unfortunately the impurities which are present in wulfenite ores are highly objectionable in the production of molybdenum and its salts, and it is difficult to dispose of them. Molybdenum also occurs in nature as an oxide, but this is not important, as the sulphide is extremely resistant to oxidation.

Molybdenum is used to a small extent as metal, but chiefly in the form of ferromolybdenum, in the making of alloy steels; in the form of ammonium molybdate as a chemical reagent, chiefly for the determination of phosphorus in ores, iron, and steel by the molybdate method; and in the form of molybdic acid for coloring porcelain, dyeing silk and wool, and in coloring leather and rubber. The total consumption is not great, the equivalent of 7.8 tons of molybdenum, valued at $15,940, having been imported into this country in 1913, and even that small quantity was nearly three times the imports in 1912, or 3.9 tons, valued at $4670.

The making of ferromolybdenum in the electric furnace has been thoroughly studied by Mr. R. M. Keeney, of the Bureau of Mines, who finds that a satisfactory product can be made direct from the ore in a single melting, using lime as a desulphurizing agent. As already said, ores for this purpose must be free from copper, arsenic, bismuth, and tungsten, and must contain over 85 per cent MoS_2 to be acceptable in the market. Most of the concentrate sold contains 90 to 95 per cent. The chief use of the ferromolybdenum is for adding to alloy steels to make them self-hardening, the resulting steel (containing 8 to 10 per cent molybdenum) being used for the making of high-speed cutting tools. It is generally claimed that one pound of molybdenum is as effective as about two pounds of tungsten for this purpose, but there is some difference of opinion as to this. Last year there was a considerable increase in the consumption of ferromolybdenum, but no adequate explanation of the reason for this has yet been advanced. As the total consumption is small it does not require a large increase in amount to create a large percentage of increase.

As to the market for molybdenite, at present it is always good, and there is a steady demand, since, although the consumption is small, the production is even smaller. Most of the world's supply of ore comes from Australia, especially Queensland. The output of this state in 1913 was 66 tons, but the production increased greatly in 1914 until the war started, the second quarter yielding 28.5 tons valued at $58,000, and the third quarter only 1.75 tons worth $4000. The deposits of this mineral, with wolfram and bismuth, at Bamford, North Queensland, are described in a report of the assistant government geologist, Mr. Lionel C. Ball. Treatment of the ore is also discussed. The war resulted in the principal markets being shut off, but the government is aiding the miners by certain advances on production. Trial lots of ore from various places in the United States and Canada have been milled at various times of recent years, without leading to a steady output. The Noble Electric Steel Company of California has begun the production of ferromanganese in its electric furnace, and if a steady supply of ore of good quality were available, could probably undertake the making of ferromolybdenum as well. Whether the market could be sustained at its present price level in the face of any marked increase in production is more doubtful. Anyone planning to develop a deposit of notable size would need to consider the possibility of having to carry on operations in the face of considerably lower prices for molybdenite than now prevail.

One of the reasons for the keen demand for molybdenum during 1914 was the discovery in France of a process for the preservation of cordite in hot climates, where this explosive deteriorates rapidly.

LOOKING FORWARD

One of the principal points in the preliminary reply of Great Britain to the protest of the U. S. government at undue interference with our foreign trade, is that shipments of copper from this country to the neutral countries of Europe have shown a great increase since the outbreak of war, and that this is clear evidence that this copper is really intended to be surreptitiously forwarded to Germany. When the matter is carefully considered with a clear understanding of all the facts involved, it appears in quite another light. In the first place, there has been no enormous increase of exports of copper to the neutral countries near Germany. The exports of copper from this country to Holland from January to the end of November 1914 were 40,000,000 lb. less than for the same period of the preceding year. While England took from the United States nearly 75,000,000 lb. more copper in 1914 than in 1913, all the other European countries bought less than they had in 1913, with the exception of Italy and Scandinavia. These countries attempted to buy somewhat increased amounts from us, but much of this was held up in transit so that Italy received almost exactly the same amount as in 1913. The Scandinavian countries received about 16,500,000 lb. more than in 1913, but the United States sold to the whole of Europe, after deducting the excess of sales to England, over 150,000,000 lb. less copper in the eleven months of 1914 than in the corresponding period of 1913. England, the Scandinavian countries, and Italy were the only European countries which increased their purchases in 1914: England bought almost 75,000,000 lb. more copper than usual. Scandinavia and Italy together actually received only 17,000,000 lb. more than in 1913, though they tried to purchase some 30,000,000 lb. more, which was detained on the high seas. These countries increased their purchases by less than 35%; England increased hers by almost 75%. If England could take care of this increased amount without forwarding it to Germany, why should it be assumed that the increase in the purchases of the other countries was necessarily intended for Germany?

The next question is why should any European country increase its purchases of copper from us at this time, and this is not hard to answer. Germany is a great manufacturing country and a large part of the finished products which it makes and exports to other countries are made from imported copper. Nearly 70% of all copper used is employed in connection with the electrical industry, and Germany's exports of electrical equipment in 1912 amounted to about 250,000,000 marks. Of copper wire alone it exported 6,608,800 lb. to England, 3,574,000 to Switzerland, 3,509,100 to Spain, 2,939,200 to Denmark, 2,600,400 to Holland, 1,632,400 to Italy, 1,526,800 to Norway, 1,491,600 to France, 1,188,000 to Belgium, and 1,107,800 lb. to Brazil. Miscellaneous manufactures, in which Germany excels, use up large quantities of copper also. The automobile business is also a large consumer of copper; the Ford Automobile Co. alone uses 15,000,000 lb. of copper in a year. Germany does a large export business in automobiles, her exports in 1912 being valued at 65,000,000 marks. In short, while Germany buys large quantities of raw copper each year, this is used to manufacture products which are sold to other countries. Now this export business is totally cut off. Two things are the result. Germany needs only a part of the copper it formerly took, and the countries which formerly bought their manufactures of copper in Germany must now purchase them elsewhere or make them themselves. English manufacturers hope to get this trade which Germany has lost, but the manufacturers in other European countries would like to have a finger in the pie also. Nothing is more natural than that the few European countries which are not engaged in the war and have much hope of keeping out of it should endeavor to utilize the present opportunity to build up their home industries.

Another factor is also involved. Norway produces some 25,000,000 lb. of copper each year, Sweden 3,500,000 lb., and Italy over 5,000,000 lb. The price of copper in Germany has gone up to 30c. per pound, as compared to less than 14c. here. There is no rule of war to prevent the mines in these countries from selling their copper to Germany, nor can the Allies prevent them from doing so, since they neither control the North Sea nor communication between Italy, Austria, and Germany. It is the most natural thing in the world that producers there should take advantage of this opportunity to realize an increased price for their copper. As a result, manufacturers in those countries have to buy a correspondingly increased amount abroad. Another point which must not be overlooked is the present activity in the manufacture of ammunition and implements of warfare all over the world. Many small countries which formerly bought these in limited amounts from the great Krupp, Creusot, and the English works, now are trying, with feverish activity, to prepare themselves in case they are involved in the war, and cannot get any arms from these works, which are fully occupied with the orders from their own countries. In Italy especially, small works which are not known to the general public, but which do a large aggregate business, are working at top speed to execute the war orders of the Italian government and other countries. A good deal of copper is consumed in the manufacture of munitions of war, and this is another reason why some European countries should increase their purchases at this time. It would not have been surprising if the American sales to these countries had increased more than they have, and the depression of general business resulting from the war is doubtless the cause of poor demand for copper abroad, as it is here.

Including its own production, Germany can obtain about 95,000,000 lb. from adjoining countries, and is resourceful enough to secure other sufficient supplies.

Lake Superior Copper Mining: Present and Future—II

By THOMAS T. READ

The fairly uniform character of the deposits of this district naturally determines the methods of mining employed and insures that there will be no great diversity among different mines. This is subject to two qualifications, for the dip of the deposits about Painesdale is so much steeper than those near Calumet that differences in the methods employed are inevitable. Furthermore, methods at the Calumet & Hecla, for example, have been modified from time to time both as a result of the changing conditions met with increased depth, and because of the advance in the knowledge of the art. Thus the Calumet & Hecla conglomerate was first mined by the pillar and stall system. Later when the square-set system was devised by Philip Diedesheimer to meet the conditions at the Comstock, it was soon after adopted by the Calumet & Hecla, and for many years was a characteristic of the operations of that mine, though it was never used by the other mines of the district, none of which possessed ore rich enough to bear the expense of so much timber. Even on the rich Calumet & Hecla this cost was a burden and the sets, at first made of the best pine, were made of cheaper and cheaper material as the price of lumber rose yearly. Finally the use of the square-set was abandoned, the general practice now being to combine stulls in the stopes with pillars near the shafts in order to keep the working places open, allowing them to cave as soon as is practicable, except where necessary to maintain haulage roads and other main passageways.

General Mining Practice

The general scheme of mining, namely of sinking inclined shafts in the vein, turning off levels at 100-ft. intervals and beginning stoping as soon as a safe distance from the shaft has been reached, has obvious disadvantages and is apt to appear irrational to operators familiar with mining practice elsewhere who visit the district for the first time. So indeed it is, but the explanation of it is found in the conditions discussed in the preceding chapter, where it was pointed out that, owing to the character of the ore deposits, practically the only way to determine whether a prospect will make a mine and the only way to develop such deposits, is by sinking, driving, and stoping in the orebody itself. The case of the Arcadian, where the owners found that they did not possess a profitable mine only after huge sums had been spent, has already been cited, and there are numerous other instances that are less frequently mentioned. The result is that, having done this exploration work as cheaply as possible in order to lessen the total invested capital in case the venture prove a failure, the general features of the mining methods to be used are by it unavoidably fixed and the large amount of work already done must be utilized, even though it is easy to see in the end that it would have been better to have done it differently.

This situation is much like that of the manufacturer who starts in business in a small way and, finding the business profitable, gradually adds to his equipment, building ells and additions here and a lean-to there, until the final plant is neither well laid out nor convenient for operation; being, as it actually is, a sort of compromise with successive sets of changing conditions. In the case of a manufacturing plant it will frequently pay to scrap such a plant and build anew, since the lessened operating cost will, during the life of the new plant, repay the cost of reconstruction, but in the case of a mine this is seldom the case, for the period to be considered is not the life of the equipment, but the life of the mine as a profitable producer, which can seldom be counted on with certainty. Quite aside from the persistence of the deposits, almost any mine in the district except the Calumet & Hecla may cross the border line of profit in a comparatively short period for reasons which will become evident in the following discussion; and, above all, there is no counting on the price of copper. For a considerable period now the price of the metal has hovered near 12c. per pound. Most producers believe that it will, within a comparatively short period, advance to about 14c., a figure which there are many reasons for regarding as about the present normal price. Though im-

TAMARACK No. 3 SHAFT.

probable, there is no impossibility involved in supposing that it may continue to decline to about 10c. per pound and remain near that figure, one at which the only dividends most of the mines of the district, and many of those of the whole country as well, could pay, would be those of the Irish variety. It is just this uncertainty which prevents the financial management of a mine being directed along as advantageous a line as that of an industrial venture, and it is my purpose to point out in this series of articles that through the concentration of the mining companies in the hands of a few strong organizations and the carrying on of operations on a large scale, it has been found possible to make mining in this district approach more closely to the security of an industrial undertaking and has assured a greatly increased productive life to the district.

Factors Increasing Mining Costs at Depth

As an example of the increase of operating cost due to working in depth along the lines laid out in earlier years the conglomerate lode of the Calumet & Hecla may be cited, where 300 men are kept continuously at work on the shaft, cutting out crushed timber, brushing down the sides and back of the shaft, putting in new timber, and repairing tracks, pump columns, and bell lines; work made necessary by the fact that the hanging and foot-walls are continually moving. These statements, as well as most of those elsewhere made regarding the Calumet & Hecla, are taken from the sworn testimony of the manager, James MacNaughton, before the Congressional Investigating Committee last March. As the total number of men employed underground in both the conglomerate and amygdaloid lodes is about 2400, assuming that two-thirds of these are employed in the conglomerate, leads to the deduction that 15% of the labor cost of mining in the conglomerate is due to the necessity for maintaining shafts in bad ground.

The details of the mining methods used in several typical mines have been given by T. A. Rickard in his interesting book, 'The Copper Mines of Lake Superior,' familiarity with which I have assumed on the part of my readers. I will not attempt here, therefore, to deal with mining in any comprehensive way, but merely refer to such features as serve to illustrate the points which seem to be of most significance as regards the future mining operations. The typical Lake Superior copper mine is operated through several inclined shafts placed from 700 to 2500 ft. apart, and generally lying either on the foot-wall of the lode or within the foot-wall near the lode, the latter being the more recent practice. There are only about a half dozen vertical shafts in the district, nearly all belonging to the Tamarack, which is not now being operated. The flat dip of the ore deposits, 30 to 40° around Calumet, does not lend itself to exploitation through vertical shafts, though the steep dip (70°) in the Copper Range properties would have led to the use of vertical shafts anywhere except in a district where inclined shafts are wellnigh universal practice. Drifts are turned off from these shafts at intervals of 100 to 125 ft., though the Quincy mine is now spacing drifts 200 ft. or more apart. It was formerly the universal custom to leave a sufficient pillar to protect the shaft and then at once begin stoping. Now, whenever practicable, drifts are driven through to the boundaries of the block to be stoped and stoping operations then retreat toward the shaft, the advantages being obvious. The more rational practice is not yet general partly because, as before mentioned, an inherited system cannot easily be changed, but chiefly because it is not the custom in the district to keep development work sufficiently far ahead of stoping to allow waiting until the development of a block of ground is complete before beginning to draw ore from it. This is discussed a little farther on.

Tramming Underground

The shafts are commonly in the lode, near the foot-wall, for most of the ore mined is taken from the amygdaloid flows in which the workable ore is commonly near the hanging wall. This usually results in keeping the shaft close to the ore and yet in fairly solid ground. The foot-wall side of the ore has no fixed position, the mine captain taking as much at any given place as his trained eye tells him will prove profitable to mill. As a result these drifts are commonly exceedingly tortuous, and one sees that tramming is practically everywhere done by hand. Two exceptions to this should be noted; the Quincy, which is in many respects the most advanced of all the mines in its practice, uses electric locomotives, and at the Superior, which the Calumet & Hecla management is now developing on a much larger scale than before, mules are used to haul back the empty cars to the faces, the full cars running to the shaft by gravity. According to the testimony of James MacNaughton the average length of haul and tons handled per day per trammer is as follows for the different mines of the district:

Hand Tramming, January 1 to June 30, 1913.

	Av. length of tram.	Tons per day per man.	Max. length of tram, ft.
Ahmeek	563	16.07	....
Allouez	753	8.86	....
Calumet & Hecla:			
Conglomerate	171	14.53	....
Osceola lode	582	19.48	....
Centennial	900	13.98	....
Isle Royale	750	14.54	....
North Kearsarge	702	13.36	1600
South Kearsarge	444	14.73	900
Osceola	850	12.71	2030
Superior	480	18.27	....
Tamarack	508	12.12	....
Average	609	14.42	....

In the above figures those given for the conglomerate lode of the Calumet & Hecla represent the average for 386 men, one-fourth of whom were working under contract and the rest on Company time. The figures for the Osceola lode are the average for 190 men, all on contract. The average daily wage of the trammers in all mines of the district during this period was $2.63 per day. It will be seen from the table that the average labor cost of tramming of 1 ton 609 ft. is 18.23c. The obvious line o[f]

development for mining practice to take is to seek some readjustment so that hand tramming can be replaced by mechanical haulage as completely as possible. Mining costs must be steadily reduced, and as the day's pay per man is likely to advance and certain not to decrease, tramming represents an item in the mining cost which cannot be decreased except by increasing the tons hauled per day per man, and this cannot easily be done except by such changes in conditions as might better be directed toward eliminating hand tramming. Wherever employed, hand tramming is a prolific source of accidents—the men get their feet beneath the wheels, their hands in the doors, and their bodies between the cars or between a car and a post. Accidents are almost unavoidable when men have to work around a heavy moving object in semi-darkness, and the best remedy is to take the men away and handle the work mechanically. Another drawback to hand tramming is the fact that it adds to the working force of the mine a considerable number of employees of the least desirable type. The work is hard, unpleasant, and comparatively uninteresting, and, except in the case of beginners who expect to advance to higher positions, it only appeals to men who are too unskillful and ignorant successfully to perform more agreeable work. Such men are the natural prey of labor agitators and those who foment industrial unrest, and to this their arduous work is a contributory cause. Hard work tends to make men dissatisfied, and a tired man does not think clearly, as is reflected in the common expression 'too tired to think.' For all these reasons mechanical haulage will doubtless be substituted for hand tramming wherever possible as soon as practicable.

Large Amount of Ground Kept Open

Another characteristic of the mining methods employed in this district is the large amount of ground which is kept open. In the Calumet & Hecla there are over 70 miles of drifts and workings, and James MacNaughton has estimated that in normal times work is under way in over 80% of these openings. The reasons for this have already been made clear. The ore shades off gradually from a copper content high enough to yield a working profit, and as lowered working costs and higher recovery reduce the minimum profitable content, material left behind in the old workings is constantly being transformed into profitable ore, and drifts are therefore kept open as long as possible, to allow access to such material, instead of allowing them to cave as soon as stoping is completed. In addition the system of beginning stoping next the shaft and working outward makes it necessary to keep the drift open till stoping is completed at its farther end, and this may be a very long time if the farther stopes are low grade. Both these features are illustrated in the accompanying plan of the workings of a typical mine. The shaded areas are the old stopes and the cross-hatched areas are those worked in 1913. It will at once be noticed that work was going on throughout nearly the whole mine area. It is perfectly possible to take the view that there is no real profit on the ore recovered from old workings, the apparent operating profit having been already eaten up by the cost of keeping these workings open. This gives ample opportunity for argument, for I do not know of any data which would definitely prove or disprove this view. It is, however, evident that the profits on ore thus recovered are at least decreased. It must not be overlooked, though, that this method of working has a speculative side which also tends to justify it. There must have been many periods in the past quarter century when there was good ground for believing that copper might advance to a much higher figure than the one then prevailing, and in that case the low-grade ore in the old stopes would not only yield a good profit, but would enable a rapid increase in the tonnage mined to be made without waiting for development work. Thus between 1904 and 1907, Lake copper advanced from 13 to 21c. per pound and then declined to 15c. in 1908. A mine which could increase its output without waiting for development work would reap the benefit of the increasing price, while a mine which pushed development work on the strength of rising prices would be likely to be caught on the drop with blocked-out stopes that could no longer be worked at a profit. It is quite probable that this factor has been of importance in causing the retention of the system of stoping outward from the shafts. The thoughtful reader will already have been struck with the idea that the present large scale mining which has grown out of the early day small scale mining has all along been hampered by the persistence of the small scale ideas and meth-

LONGITUDINAL SECTION OF

ods of the early miners. This is both natural and to a considerable degree inevitable; the managements of the various companies are working away from its influence as rapidly as possible.

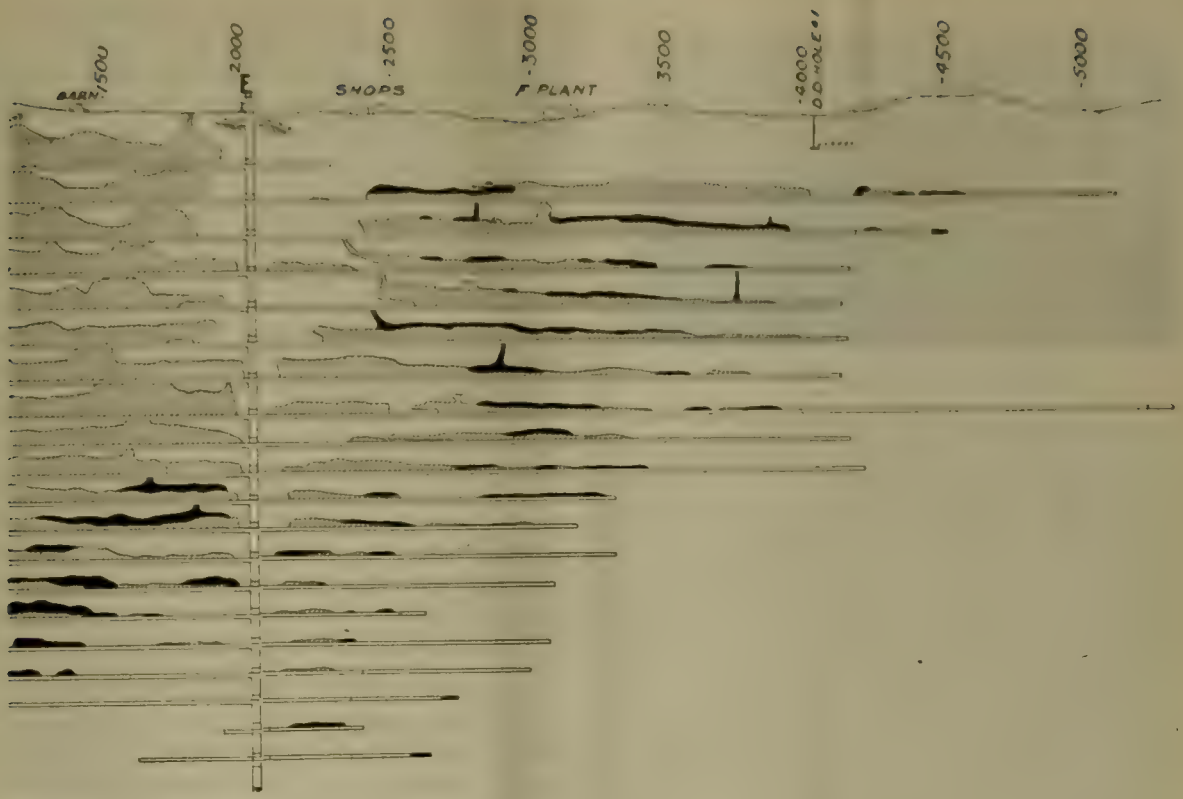
One-Man Drills

Drilling and breaking the ore in these mines has been the source of much interest, since the cost of doing this work has been so successfully reduced in the past few years, while the means adopted to secure this desirable end figured largely in the causes alleged for calling the strike in 1913. Until recently it was the custom in the mines of the district to use an ordinary Rand drill, weighing about 300 lb., and drilling a comparatively large hole, in stoping operations. As the post, base, and other accessories weigh about 300 lb. more, it was necessary for the two men constituting a drill crew to haul a weight of 600 lb. up to the face of the stopes (inclined 35° or more), and a large part of the energy expended and time worked by these men was devoted to the useless handling of heavy weights.

Charles L. Lawton, manager of the Quincy mine (who was largely responsible for the introduction of light drills for stoping in the Cripple Creek district) has always maintained that the use of large deep holes in breaking ground is unprofitable, since less mechanical work is required to cut a small hole, while the use of strong dynamite permits a small hole to be charged with the same explosive force per foot of hole as a larger hole with weaker dynamite. If a hole is started small it cannot be drilled deep, as the finished hole will then be too small, but as it is not customary to use very deep holes underground, for a variety of reasons, this does not materially affect the use of the smaller drill. By using a small drill it is possible to strike a greater number of blows per second, and the force of the blow is nearly as great as with a heavier weight of striking parts. It is evident that this is a more economical way to use the compressed air, since a large number of light sharp blows are obviously more effective in chipping away the rock than fewer heavy blows, which tend to spend their force largely in 'stunning' the rock. Mr. Lawton secured the co-operation of the Ingersoll-Rand Co., with the result that there was developed and put into use in this district the type of light or 'one-man' drill now so widely known. This type of drill weighs less than one-half as much as the old style reciprocating piston drill and can therefore be handled by one man, though it is standard practice to work drills in pairs and the men aid each other in setting up the drills. The light drill cuts more rapidly, less time is lost in setting it up and moving it, and only one man is employed per drill instead of two.

Wages Earned: One-Man v. Two-Man Machines

The economy thus effected has many ramifications As the drill does not reciprocate in the hole, its edges do not wear down so fast and a single drill will serve to drill a greater depth of hole before needing to be re-



CHAMPION MINE WORKINGS.

placed. It is therefore not necessary to sharpen so many drills, which makes less labor in the blacksmith shop, and less labor is required in taking dull drills out of the mine, and carrying sharp ones in. The light drill, for the reasons already mentioned, is capable of drilling considerably faster than the heavy drills, and according to the testimony of James MacNaughton, the average footage drilled during a shift with the big drills is 32 to 38 ft., and with the light drills 40 to 48 ft. In order to predispose the miner toward the use of the better drill the wage scale has been adjusted so that miners using the light drill earn 15 to 18% more than miners using the big drills. The following data are taken from the testimony of James MacNaughton:

CALUMET & HECLA, YEAR ENDED DECEMBER 31, 1912

	No. of shifts.	Labor cost.	Supply cost.	Average wage.
One-man drill	54,758	$ 193,936	$ 94,058	$3.34
Two-man drill	350,012	1,024,802	291,526	2.83

In the Calumet & Hecla subsidiaries, from January 1 to June 30, 1913, the average wage per shift for the one-man drill was $3.54 and for the two-man drill $3.10. The tremendous saving in labor cost of breaking the ore is well indicated by the table above. In round figures it may be said that the use of this drill has reduced the cost of breaking the rock in the stopes to one-third of what it formerly was; say to 15c. per ton as compared to 45c. per ton, in spite of the fact that the companies have made an increase of 15 to 18% in the wage scale of the men operating the light drills. Further reductions in the cost of drilling and breaking ore in the stopes can doubtless be made by intensive study, but they will necessarily be comparatively slight, and a further reduction comparable to that made by the use of the new type of drill can scarcely be hoped for. It is interesting to note in passing that some part of the saving made by the use of these drills is due to the simultaneous introduction of 'efficiency' methods and motion study. Thus it was found that the habit of the miners of throwing down dull steel into a heap with sharpened steel led to a considerable loss of time in changing bits through the miner rummaging through the heap in the endeavor to find the bit next required. By keeping the sharp bits separate from the dull ones and standing them up in order from short to long, it was found possible to considerably increase the footage drilled per shift. A force of young technical graduates provided with stop watches have been employed to study drilling as well as general underground work, in the Calumet & Hecla properties, and as a result of their suggestions many economies have been effected. The importance of this line of work on the general future of the district is so evident as to need no comment.

CAR-LOADING SYSTEMS

Another field for progress in which less advance has yet been made is the elimination of manual labor in the loading of cars with ore. In his book on the mines of

CENTENNIAL No. 1 AND 2 SHAFTS.

this district, familiarity with which by the reader I have assumed. T. A. Rickard has described the methods in use ten years ago, which have not since been materially changed. The irregular topography of the foot-wall in these deposits has already been emphasized, and it is evident that it renders necessary a certain amount of shoveling in the stopes. A great amount of study has been devoted to the possibility of getting the ore broken at the stope faces into the cars, running on tracks in the main level, by purely mechanical means. Little success has yet been attained, but a moment's reflection on the astonishing changes which have been brought about in mining practice during the past 25 years effectually serves to prevent entertaining the belief that this problem cannot be solved. As elsewhere discussed, the proper line of progress for practice in the district seems to lie along the substitution of a small number of men, at higher wages, for large numbers of lower-grade men at less wages, and this department of underground work is one of those in which the opportunities for elimination are greatest.

Filling Worked-Out Stopes

What may be considered as the greatest problem of all is the support of the excavations made in mining. The method followed by the Calumet & Hecla in its conglomerate lode workings was the use of timber, and it has already been indicated how the cost of this method is a burden which the low-grade mines, the type of future practice, cannot hope to assume. In a preceding article I have pointed out that the typical rocks of the district are a series of volcanic flows, essentially homogeneous in character and usually of considerable thickness. The rock layers overlying the ore deposits are therefore relatively strong as compared to the usual overburden in coal mining practice. The overlying rocks above a coal seam often contain strong layers of sandstone or limestone, but these are usually intercallated with layers of shale or other material of comparatively little coherence. When subsidence takes place, a few strong layers are involved, but the maximum of fracturing, and consequent expansion to fill the open space left by removal of the coal, takes place in the less coherent beds, so that the process is a gradual one which exhibits little violence. Even under these conditions the problem is a serious one, and the United States Bureau of Mines is devoting a considerable portion of its energies to its solution. The strength of the overlying rocks in the Lake Superior district is such that large stoped areas can be left with comparatively little support for long periods of time. In the Atlantic mine, in which for many years the mining costs were the lowest of any in the district, advantage was taken of this to permit mining out the full thickness of the lode, up to within 12 or 15 ft. of the level above, using stulls to protect the working level. For twenty years the mine was cheaply and successfully worked, but in 1904 the overlying rocks began to subside with such violence as to produce miniature earthquakes, and the air in the stopes was driven out with the violence of a coal mine explosion, wrecking the shafts, and within two years the mine was lost, although some 6,000,000 tons of ore still remained unmined. A somewhat similar though much less serious state of affairs now exists in the Quincy mine, which has been worked with unusual skill, and it is abundantly evident that the stoping out of large areas, providing only sufficient support to hold up the roof for a comparatively few years, is not a method which can be safely followed.

Caving and Other Methods Possible

One of two methods might be used to overcome this difficulty. The mines might be worked by caving methods, bringing down the roof into contact with the foot-wall as fast as the ore is removed; or the stopes may be filled. Caving methods have been considered, but present much difficulty. As already noted, the usual practice in the district is to work outward to the boundaries of the property, and the reasons for this have been indicated. In working by caving methods it is usually necessary to begin at the boundaries and work back, therefore the general plan of mining operations would require to be altered. The vital difficulty, however, is the strength of the overlying rocks and the fact that the moderate dip of the strata makes it necessary to set in motion greater and greater thickness of strong rock as the workings extend in depth. In ordinary caving work the overburden is, by careful work, brought into what may be called a fluid state, and it then follows down as the workings proceed in depth without causing any trouble. But in caving the overburden on these deposits it will not follow down on the stope with any degree of freedom, as the dip is not steep enough, and an attempt to cave great thicknesses of strong overburden would lead to the same condition of affairs as that described above. In the district around the Painesdale, where the dip of the lode is steep, caving could seemingly be employed, but for the district as a whole it seems impracticable.

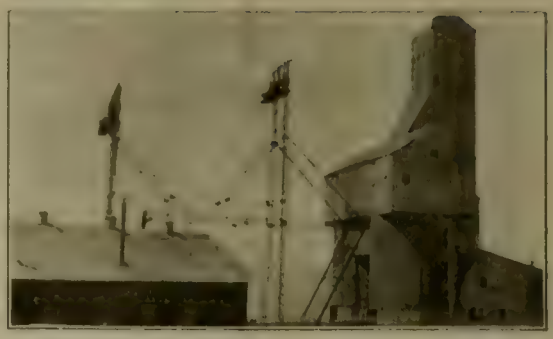
There remains, then, the falling of the stopes. This is also a difficult problem. No dependence can be placed on waste rock sorted out underground, for the amount of waste is in any case too small for this purpose, and the preceding discussion has, I hope, served to indicate my belief that the destiny of this district lies in large scale.

low cost work and the elimination, so far as possible, of human labor. Material must be brought into the stopes for this purpose. This cannot be derived by breaking it elsewhere underground, as the net result of such a method would be similar to 'robbing Peter to pay Paul,' and it is, in addition, expensive. The material must be brought from the surface. This involves three difficulties: the procuring of the material, the conveying of it underground, and its distribution in the stopes. The surface of the ground about these mines is in most cases nearly level, or gently rolling, and to secure material nearby would involve digging a hole which would introduce a problem of its own, especially as the surface is of considerable value for its present purposes. A promising start along the most logical line has been made by F. W. Denton, manager of the Copper Range properties, who has begun to use the sand from stamp-mills for filling. While the mills are at some distance from the mines it is cheaper to haul back the ore cars (which have to return anyway) loaded with sand than to attempt to secure filling nearby. A simple elevator attached to the tailing launder raises the tailing to a bin, from which it can be drawn into the cars at but a small total cost. At the mine a series of winzes near the working shafts have been constructed just beneath the railway track which serves the ore-bins. The car of sand is brought above this hopper, its content discharged, and it then moves on to receive its load of ore.

Sand-Filling Difficulties

Difficulties that will at once suggest themselves to any mining engineer do not fail to appear, but not exactly in the order of importance that might be supposed. There is but little trouble from the moisture in the sand, as the method by which the cars are filled insures that only the coarser material is discharged into the cars, and by the time it has reached the mine the sand has pretty well dried out. There is some chance, of course, that in winter time freezing may take place before the water drains away, and it will be interesting to see the results of experience during the coming winter. In order to transport the sand to the stopes and distribute it therein, the ingenious method of forcing it through pipes with compressed air has been adopted; a 2-in. pipe has been found more satisfactory for this purpose than a larger

BALTIC No. 2 SHAFT.



HANCOCK No. 2 SHAFT.

one. No trouble is experienced from the little moisture remaining in the sand, but it exhibits a tendency to pack in the pipes where its movement is interrupted. This has apparently been overcome by using 'booster' jets of air at intervals throughout the length of the pipe, and by enclosing the sand-hopper at the level in an air-tight box. The use of the sand is here supplementary to filling with waste rock, as described in 'The Copper Mines of Lake Superior.' The management of the Copper Range properties has always been progressive and will doubtless continue the study of the filling problem until a thoroughly satisfactory method is developed.

It has been suggested that the sluicing of loose material into the workings through boreholes, as devised in Pennsylvania many years ago and more recently extensively applied in Germany and South Africa, could be utilized. It scarcely seems practicable, however, as none of the mines have supplies of loose material available for the purpose, and if tailing is brought back from the stamp-mills, as described above, there is no advantage in introducing with it into the mines large quantities of water which would have to be pumped out again, besides making the workings unpleasantly wet. It must not be overlooked that the great depth of these mines greatly complicates the problem of filling them, and the tremendous extent of the workings is also an important factor. I can do no more here than state the problem; someone writing a decade later will doubtless be able to describe the way in which it was solved.

One more factor must be mentioned. The next article in this series will describe how the accumulated tailing from former milling operations has been converted into a considerable asset by the improvements in metallurgical methods devised by C. H. Benedict. Tailing used for mine filling is placed beyond recovery, and except in those cases where its copper content has already been reduced to below the hope of any further profit the copper thus lost is a charge against the cost of filling.

There are many other features of Lake Superior mining practice which are of interest, but it would unduly prolong my discussion to refer to them all in detail. Those mentioned are the ones which seem to me of most significance, and I will therefore conclude with some tables of comparative data (for which I am indebted to

the courtesy of E. N. Skinner*), which will serve to illustrate the points which I have attempted to set forth above.

CALUMET & HECLA, 1905 TO 1910

Production:	1905.	1906.	1907.	1908.	1909.	1910.
Daily output of ore, tons	5445	7475	8325	8025	8670	9175
Yield per ton, conglom., lb.	51.77	46.96	41.90	39.68	35.03	32.25
Yield per ton, amyg., lb.	22.00	19.51	19.00	18.45	17.06	15.85
Costs:						
Mining and milling, cents per lb. copper	6.62	7.64	7.05	7.65	7.33	6.55
Smelting and selling, cents per lb. copper	1.10	1.10	1.10	1.10	1.10	1.10
Construction and expansion	0.45	1.05	9.82	5.04	0.12	0.35
Total costs	8.17	9.79	17.97	13.79	8.55	8.00
Profit:						
Average price copper, cents	14.09	17.24	22.15	17.18	13.59	13.33
Profit per lb. copper, cents	5.92	7.45	4.16	3.39	5.04	5.33
Profit per ton ore	$2.99	$3.64	$1.33	$1.07	$1.52	$1.34

The data given above are not strictly comparable, as the methods of bookkeeping vary greatly, but are of much interest, nevertheless.

The Mekeel Tunnel

By CHARLES S. SHAUNESSY

†The Mekeel tunnel is one of the short-grade tunnels of the Catskill aqueduct, being a part of the work for an additional water supply for the city of New York. It is situated in the highlands on the Hudson.

The dimensions of all grade tunnels of this delivery conduit were the same, being designed to carry over 500,000,000 gal. per day, or doubling the present supply of Greater New York.

The tunnel is 1003 ft. long and 13 ft. 4 in. by 17 ft. in cross-section, and was driven entirely from the north portal. The rock for about one-quarter way was gneiss, disintegrated in places, but not sufficient to require timbering except at the portal, where some shoring was done. The direction of the tunnel was approximately at right angles to the predominating planes, thus favoring a good breakage. The remainder of the rock was gray granite, very fine grained, high in quartz, and interspersed with joint planes and mud seams in various directions. Running through it at intervals were bands from one to four feet wide of pegmatite, an intrusive rock of very coarse grain and exceedingly good drilling. The tunnel was exceptionally dry, and water had to be brought in for the drilling operations, although after driving, small quantities appeared in the roof.

The general method of driving was with a top heading about 10 ft. high, representing the upper half of the tunnel section, the lower half or bench approximating a rectangle. Three Murphy drills, size 3½ by 7½ in., were set up on two 7-ft. columns in the heading, and on the bench two tripods were used of the same size and type. Special efforts were made to keep close to the minimum line and maintain the required clearances in the heading, thus avoiding the most expensive part of the trimming. Drilling in the gneiss gave little trouble, and some good records were made. The highest rate per drill per day was 86 ft. when conditions were good. For the entire tunnel the daily rate per drill was 30 ft. The contract price was $3.27 per yard.

*'Mining Costs of the World,' now in course of publication.

†Abstract from *The Tech. Monthly and Harvard Eng. Jour.*

Organization at the Treadwell Cyanide Plant

Co-operation between officials and men, and among the latter themselves, is highly desirable in any industry, as it tends toward a better feeling and subsequent efficiency. Employees often work mechanically, doing what is required above reproach, yet knowing little or nothing of the results of their operations. This is in some respects not fair to the worker, who gets into a groove and only thinks of finishing his shift. In smelters, stamp-mills, cyanide plants, and large concentrators, no harm results from giving out information to the men, so that they see defects in the machines under their care, or in their own supervision. The accompanying chart, furnished by W. P. Lass, is a new style of organization flow-sheet posted in the Alaska Treadwell cyanide plant at Juneau, showing the relationship of the whole staff, or the order of precedence of each person. The table shows the detailed method of reporting the daily operations of this plant, and is a copy of one placed on the wall and filled in each day by the cyanide plant accountant. Data which may be of interest to the men are available for study. The chart has done much to stimulate the interest and co-operation of the men. There are no secrets held by the Treadwell company, and employees share in the knowledge of what is being done.

The Company manages what is known as the Treadwell Club, which continues to be very popular with the employees, and is considered an important adjunct to the plant. A boarding-house is also maintained, which, although very desirable for the Company, is run at a small loss each year, but this is more than made good by the extra satisfaction given employees. Those who board there are charged $25 per month for meals, and $2 per month is added when they occupy a room in the Company's lodging house. Wages in the surface plants

are as follows: amalgamators, $120; feeders, $100; and vanner men, $95 to $130 per month. Machinists and helpers in machine-shop, $3 to $7; blacksmiths, $5 to $6; tool sharpeners, $4.50; and blacksmith's helpers, $3 per day. In 1913 there were 719 men employed on the property, who averaged $3.51 per day.

Latent Possibilities Among California Mineral Resources

By E. S. BOALICH

Much has been said and written in recent years regarding conservation and development of the natural resources of the United States. It has long been recognized that the possibilities along many lines, notably as regards minor mineral products, are far in advance of development. This means from a commercial viewpoint that the people of the United States are buying foreign materials and sending money out of the country for products which exist here, but have so far been inadequately exploited. California is probably the leading state in the Union in regard to extent and variety of her mineral resources. All the world knows of California's gold, and more recently of its petroleum. Few, however, realize the actual variety of the mineral deposits to be found here which have potential commercial value.

A combination of circumstances has occurred, the result of which, if taken advantage of, should go far toward strengthening the position of the mineral industry in California, and incidentally that of the entire Pacific coast and tributary western states. The beneficial results of the Panama canal need no enlargement. California now has water transportation to the eastern centres with the attending low freight rates. In addition, however, the European war bids fair to spur on the normal and expected advance in many hitherto dormant lines, either immediately or in the near future, in ways undreamed of only a few weeks ago.

Five items have been selected from among several of those which (1) have been imported to a large extent in the past; (2) have a small, if any production in California or the country at large; (3) occur in California and, subject to ordinary mining conditions, should be commercial possibilities under present circumstances. The consumption of these particular substances in the United States reached a total value of about $7,500,000 during 1913. Of that amount only $200,000 worth was produced in this country.

Seven million dollars worth of antimony, asbestos, chromite (chromic iron ore), magnesite, and magnesium will be needed in domestic industries during the next twelvemonth. These are but examples. The annual imports of potash, nitrates, arsenic, bismuth, mica, mineral paints, pyrite, and abrasives amount to many millions of dollars in value. Of the five items in question, foreign sources have been partly or wholly cut off. Figures for output and imports for 1913, except as noted, are given in the following column.[1]

Mineral.	U. S. production.	Imports.
Antimony	No ores mined.	$1,053,530
*Asbestos	$ 87,959	1,819,871
Chromite	2,854	625,740
Magnesite	77,056	1,812,759
Manganese ore	40,480	2,029,680
Totals	$208,349	$7,341,580

*1912.

To assist in promoting development, the distribution of these minerals in California will be briefly mentioned. Only the more important locations can be listed and, as prospecting for these minerals has not been active, the list is doubtless far from complete.

Antimony.—No commercial production in the United States in 1913; value of imports, $1,053,530; principal use, as an alloy with lead; price (of metal), November 1914, 15½ to 18½c. per pound; occurrence in California: Colusa county, stibnite found with cinnabar in Manzanita mine; Kern county, has been mined in San Emidio cañon, near Havilah; Napa county, at Manhattan mine; Riverside county, found near Corona; San Benito county, at Stayton mine.

Asbestos.—Value of the United States production, 1913, $87,959; value of imports, $1,819,871; uses, many and well known; price, roughly from $20 to $200 per ton; occurrence in California: Amador county, various prospects; Butte county, has been mined to small extent; Calaveras and Nevada counties, various prospects; Placer county, has been mined near Auburn; Plumas county, various prospects; Riverside county, has been mined in San Jacinto mountains and elsewhere; Shasta county, has been mined near Simms station; Siskiyou and Trinity counties, various prospects.

Chromite.—Value of the United States production, 1913, $2854; value of imports, $625,740; uses, in alloys, pigments, dyes, for refractory purposes, in chemistry, etc., price, roughly $8 to $10 per ton; occurrence in California: Alameda county, has been mined southeast of Livermore; Amador county, occurs near Jackson; Calaveras county, has been mined near Valley Springs, Campo Seco, and elsewhere; Del Norte county, occurs in Rattle Snake mountains, at French Hill, and Low Divide mines; El Dorado county, prospects; Fresno county, has been mined near Sentinel; Glenn county, Black Diamond mine near Newville; Lake county, east of Middleton; Los Angeles county, near Lang station; Marin county, west of San Rafael; Mendocino county, in hills west of Russian River valley; Monterey county, prospects; Napa county, east of St. Helena; Nevada county, near Nevada City, Washington, and Coyote Diggings; Placer county, has been mined near Iowa Hill and elsewhere; Plumas county, near Meadow Valley; San Benito, San Luis Obispo, and Santa Barbara counties, various prospects; Santa Clara county, near San Jose; Shasta county, has

[1]For further information, see the publications of the U. S. Geological Survey, especially 'Mineral Resources of the United States' for various years, and *Bull.* 585, 'Useful Minerals of the United States.' Also the publications of the California State Mining Bureau, *Bull.* 38, 'Structural and Industrial Materials of California,' and *Bull.* 68, 'Mineral Production for 1913.'

been mined on Shotgun creek, Sierra county, near Downieville, Siskiyou county, mined at Chromite station and Dunsmuir; Solano county, prospects; Sonoma county, has been mined near Cloverdale; Tehama county, has been mined on Elder creek, Trinity county, near Hayfork on Trinity river; Tulare county, near Portersville and elsewhere, Tuolumne county, southwest of Sonora.

Magnesite.—Value of the United States production, 1913, $77,056; value of imports, $1,812,759; uses, as refractory substance, in paper manufacturing, making CO_2, manufacturing of oxychloride cements, miscellaneous applications—crude, calcined, and refined; price, variable; for crude ore, which is but little marketed, about $8; for calcined product, roughly from $15 to $25 and up; occurrence in California: many deposits of problematical value occur in the Coast Range from Mendocino to Los Angeles counties; a few in foothills of the Sierra Nevadas, usually as veins in serpentine; Fresno county, mined at Kings river, east of Sangor; Kern county, east of Mojave; Napa county, has been mined in Chiles and Pope valleys; Placer county, has been mined at Iowa Hill and elsewhere; Riverside county, mined near Winchester; San Benito county, on Larious creek; Santa Clara county, has been mined near Livermore; Sonoma county, has been mined near Cloverdale; Tulare county, mined at Tule River, east of Portersville; also at Harker's place, northeast of Portersville.

Manganese ore.—Value of the United States production, 1913, $40,480; value of imports, $2,029,680; uses, alloy with iron, etc., many chemical uses, as a dye and coloring material, medicinal; price, roughly from $10 to $50 per ton, depending upon quality of the ore and use for which it is intended; occurrence in California: Alameda county, has been mined on Cedar mountain, east of Livermore; Calaveras county, northeast of San Andreas; Colusa county, St. John mountain; Marin county, west of Sausalito; Placer county, near Colfax; Plumas county, southwest of Meadow Valley; Riverside county, in Maria mountains, northeastern part of county; San Luis Obispo county, west of town of San Luis Obispo, Tuolumne county, two miles north of Sonora, also 'bog manganese,' near Columbia.

A Weir in Burma

That engineering is much the same the world over is well evidenced by the accompanying illustration. This shows a weir built in Burma, near Rangoon, for the purpose of determining stream flow preliminary to the installation of a Pelton-Doble water-wheel. The instrument man is a native engineer, in the employ of a placer mining company composed largely of Indian capitalists. The weir is built of teakwood, cut on the ground. Teak, freshly cut, has a pungent odor, and exudes an acrid sap, both of which are very repellant to ants, mosquitoes, and other insects, which property renders it doubly suitable for reconnaissance structures. Its construction would be a credit to any engineer. The end contractions are carefully made, and the dimensions of the notch are correctly proportioned to the stream bed. As a touch of Eastern mysticism, 'find the rodman.'

A WEIR IN TYPICAL JUNGLE COUNTRY.

German Iron and Steel Industry

According to a cablegram from the American consulate-general at Berlin, dated January 8, figures just made public by the German Union of the Iron and Steel Industry give the November 1914 production of steel at 900,026 metric tons, against 900,201 tons in October. The total output of steel for the first 11 months of that year was 4,023,713 tons. The pig iron production of Germany was 788,956 tons in November, as compared with 792,822 tons in the preceding month; that for the first 11 months of 1914, 13,535,666 tons, contrasted with 17,697,922 tons in the corresponding period of 1913. Trade journals report the Solingen industry in steel goods and cutlery quiet, because of the falling off in exports to the United States.

The Pato and Nechi Placer Properties, Colombia

By W. A. PRICHARD

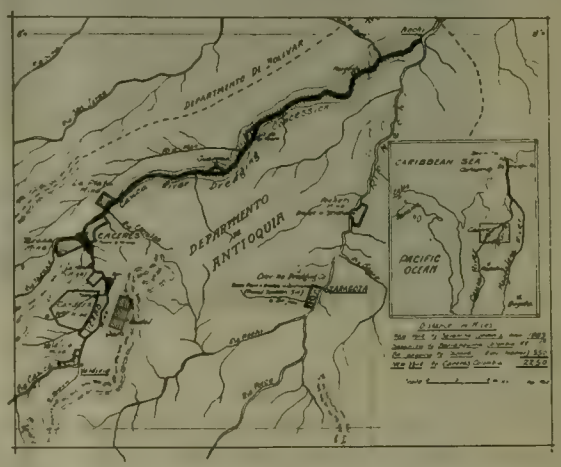
These properties are situated on the Nechi river in the department of Antioquia, Colombia, Central America. As a result of 12 months' examination of the Pato area, during which time 291 Empire hand-drill prospect holes and six shafts were sunk, the prospected areas undredged at October 1, 1914, are estimated at 528¾ acres with an average depth of 26.3 ft., and an average recovery value of 31.6c. per cu. yd. This area is calculated to contain 22,419,490 cu. yd., with a gross value of $7,092,100. The field operating cost of dredging on the basis of one dredge at Pato and one at Nechi, after 12 months from October 1, 1914, and two at Pato after 18 months from that date, is $1,744,462, leaving an estimated net return of $5,347,638. In calculating the present dredging area of Pato, I have used the results of 89 holes drilled under my supervision, 38 drilled under C. H. Munro, six drilled by A. P. Rogers, and one drilled by E. B. Kimball.

The average yield of the gravel handled from the time the dredge reached the prospected area up to the present, has been more than double the estimated average value of the dredging area.

In the drilling of this ground the drill-holes were not sufficiently close together to more than indicate that the gravel was profitable. In this part of the property there was only about one drill-hole to each 10 acres. The richest gravel formed a strip which was 500 ft. wide, and was only penetrated by two or three holes. That the dredge struck the richest ground first was due to the lay of the land, there being no other approach to the prospected area from the river at the time the boat was erected. Higher than average yields are expected to continue until in the spring of 1915, when lower average yields may be expected.

Outside of the prospected areas small extensions can be expected beyond the outlined boundaries. Between the estimated area and the Nechi river there is a fair amount of low ground that will probably prove profitable, as indicated by the results of the dredge which, although not reaching bedrock, returned from 15 to 33c. per yard for a considerable stretch in its hurried progress from the point of its construction to the tested area. There are a few acres of this ground along the river too deep for the Pato dredge, for which the Nechi dredge could be utilized after exhaustion of the Nechi ground. The future dredging prospects of Pato, therefore, outside of the tested areas, while indefinite, are by no means negligible. Aside from these exceptions, no important asset has been discovered.

The gold-bearing gravel benches have at one time covered several square miles of the Pato property, but these are now very much cut up and depleted by ancient workings. Only detached areas of the poorest gravel have been left. California hill, with an area of 13¾ acres, and an average depth of 45½ ft., is the largest and richest of these deposits. Eight drill-holes and two shafts sunk on this area give it a total of 1,008,200 cu. yd. with an average value of 19.7c. per cu. yd., making a gross value of $198,970. To work this deposit, it would be necessary to pump the water from the Nechi river, necessitating a mile of pipe-line, electric-driven pumps, and hydraulicking equipment. I understand that on a hydraulic property being operated higher up the river, it requires 17-cent ground to pay operating expenses, although that property has a water supply under gravity head. It is obvious on this basis that the margin of profit, if any, to be obtained from California hill is small. However, as there appears to be a small hydraulicking deposit on the Nechi property, the Pato



MAP SHOWING SITUATION OF PROPERTIES DESCRIBED.

management may later on have an opportunity to obtain figures from local operations that would justify the equipment of California hill and the working of it as a small side issue. At the present time, California hill is used for the camp, and is occupied by about $25,000 worth of buildings.

The yardage capacity of the Pato dredge varies with the amount of clay in the material handled, and the depth and character of the gravel. During July and August, 1914, the yardage was 128,488 and 139,547, respectively, working under fairly normal conditions. These were the first months of operation with the dredge pond water in a condition of positive control by means of a dam across Pato creek, completed in July 1914. Prior to this time the dredge depended on the elements, resulting in muddy pond water during the rainy periods, and a total stoppage in the dry periods. The muddy water caused enormous wear on pumps, etc.,

*Report to the Oroville Dredging Co., Ltd., of London, December 24, 1914.

with heavy losses of running time and heavy cost for renewals and repairs. The high average operating cost of 17.71c. per yard for the 11 months from October 1, 1913, to August 31, 1914, was due chiefly to this cause. For July and August the cost was 10.25 and 11.52c., respectively, including some extraordinary expenses. A pumping plant is being installed to aid in dredging the higher ground. It appears from recent operations that the average dredge capacity is over 125,000 cu. yd., but to be conservative I have estimated the operating cost on the basis of an average of 100,000 cu. yd. per month.

With one dredge bearing all of the overhead expense of management, power, etc., the field operating costs should never exceed 11c. per yard exclusive of bullion realization. After the Nechi dredge begins operating, bearing its proportion of the overhead expenses, the costs for Pato should not exceed 8c. per yard, exclusive of bullion expense. With two dredges on Pato and one on Nechi the cost for Pato should be about 7½c. per yard inclusive of bullion realization, which amounts to about 0.7c. per yard on a yield of 32c., or 1½c. on a yield of 70c. per yard.

It would require 20 years, more or less, for the present dredge to exhaust the estimated area of dredging ground on the Pato property. It is not likely that the dredge will last that long, even without taking into account the probable additional ground. Aside from this, I believe that a direct saving of 1½c. per yard to Pato and 1c. to Nechi could be made by distributing the fixed expenses over three dredges instead of two. An advantage can be gained by adding a dredge at this particular time, in that the construction could follow on the Nechi dredge. This would make a considerable saving in being able to continue the employment of the skilled mechanics now on the ground, who were taken out at considerable expense, and in the use of the building arrangements, etc., prepared at considerable expense for the erection of the Nechi dredge. I therefore recommend the addition of another dredge to the Pato property as soon as possible. The new dredge should be of the same capacity as the present Pato dredge, with interchangeable parts.

The Pato and Nechi properties lie in an oval basin surrounded by crystalline rocks. This basin has been cut through by the Nechi river, which separates the two properties. Within this basin are flat tables of gravel deposits whose edges form terraces. The bedrock of each of these gravel benches is clay, either red or blue according to exposure, in which are included beds of peat or brown coal. Each of these gravel benches is a reconcentration of the bench above it, and represents a former stationary level of the river. California hill is a remnant of the upper bench. Below this was a lower bench whose bedrock stood above water-level. These two benches have been nearly removed by erosion and ancient workings. The third bench, partly submerged, forms the greater portion of the higher dredging ground. The fourth bench is that being dredged now and is nearly submerged. The fifth bench, wholly submerged and covered with recent river sand, is the dredging area of the Nechi and some of the Pato not thoroughly prospected. Below this on the Nechi River bank we know from Mr. Rogers' drill-hole No. 1 that there is still a sixth layer of gold-bearing gravel between the depths of 66 and 74 ft. We know nothing yet about what occurs below this. The outer and higher bench gravel is on the clay which lies directly upon the rim rock, but toward the centre of the basin, where we encounter the lower layers of gravel, nothing is known of the ground under the clay which we assume for dredging purposes to be bedrock. In this connection I would recommend that the management dig into the bedrock from time to time with the dredge, on the chance that the supposed bedrock may be in places on an intermediate thin seam of clay. Since each successive gravel bench, as we go downward, is richer, it is possible that deep drilling may disclose ground rich enough for successful drift mining. I do not, however, attach much importance to this possibility.

The gold is of fairly uniform sized thin flakes. It is easily saved by amalgamation. There is but very little black sand, of which the most valuable portion is caught by the dredge, and saved for further treatment.

The Pato property is equipped with its own hydroelectric power plant, one 8½-cu. ft. dredge, an ice plant, and a complete repair shop. The power plant contains three 600-hp. Pelton-Francis turbines under a head of 87 ft., which drive three separate electrical generators of 300-kw. capacity each.

The Pato boat is an all-steel, close-connected, 8½-cu. ft. bucket dredge. Aside from an obvious mistake in design of the hull, which has caused it to sink twice, the dredge has proved very satisfactory. The mistake in the hull is being remedied by the addition of pontoons.

Regarding the climate, the days are disagreeably hot and steamy, the temperature ranging between 70 and 90°F. It rarely rains in the daytime. The nights and early mornings are cool and pleasant, except for parasitic and insect pests of many descriptions. During nine months of the year it rains nearly every night, and at times as much as 9½ inches in a few hours.

The Nechi property, which will be operated by the Pato company's managerial staff and supplied with power by that Company, has been prospected by 41 drill-holes, the first of which were sunk under the direction of the Pato management, while the last few holes were drilled under my supervision.

The dredgeable area as prospected to date is estimated to be 89¼ acres of an average depth of 47.6 ft. and an average value of 71.86c. per cubic yard, which should produce 6,855,900 cu. yd. of a gross value of $4,926,600. The field operating costs of dredging on the basis of one dredge operating on Pato six months, and two dredges on Pato after that period, is estimated at $554.472, leaving an estimated net return of $4,372,128.

In estimating the drill-hole results on the Nechi property, it was not possible to obtain corroborative results

as in the case of Pato, so we used a theoretical drill factor of 238 ft. of hole to the cubic yard, giving a lower value. If the Pato factor were used, the average value would be considerably higher, and I confidently expect the Nechi dredge to produce more than the estimated value. A gold fineness of 860, determined by assay, was used in the calculations of drill results.

To the south of the estimated ground there is a swampy area that has not been sufficiently drilled to determine its value. The few holes that were drilled as shown on the map indicate the probable existence of a few acres of dredgeable ground.

Up to the time of purchase of this property by the Company, the native owner was working the bench gravel deposit upon it in a small way. Sufficient drilling has not been done to determine the extent or value of this deposit. It has the appearance of being of sufficient size and value for profitable working by hydraulic methods. I recommend that the mine staff investigate this deposit at a favorable time.

The buckets of the Nechi dredge are of 7½-cu. ft. capacity. The Nechi dredging ground, however, contains less clay than Pato, and, being deeper, the buckets will average fuller than on the Pato dredge. The Nechi dredge should, therefore, handle as much or more yardage than the Pato dredge. To be on the conservative side, I am estimating the costs on a basis of 100,000 cu. yd. per month. The Nechi dredging area is agricultural land with very few trees. The cost of clearing should, therefore, not exceed $100 per acre. Pond water will be obtained by connection with the Nechi river, thus the cost for pumping pond water will not enter into the Nechi costs. I have estimated that the Nechi field operating cost will average not over 9c. per cu. yd. for the period during which only one dredge is working on Pato, and 8c. thereafter with two dredges operating on Pato. These figures include 2c. per yard for bullion expense.

An all-steel hull, close-connected, 7½-cu. ft. bucket dredge was ordered in England from Fraser & Chalmers. The hull arrived in Colombia in November and is now being put together at the Pato machine-shops. The machinery for this dredge has been delayed by the war, but will shortly leave England for Colombia. This dredge is designed to dig to a depth of 55 ft. below water-level and to handle a 10-ft. bank. It is impossible to say when this dredge will be in operation.

MINERS' SAFETY LAMPS have nearly all been imported from Europe, but, according to James W. Paul of the U. S. Bureau of Mines, numbers are being manufactured in this country, equal to those of foreign origin. This is the result of a policy of the Bureau. Glass chimneys for collieries in England were obtained from Germany, but orders are now received in the United States for these for use in England.

THE New York Assay Office handled $60,616,438 in 1914, compared with $34,283,992 in 1913. The increase was due to large gold exports early in the year.

Burro Mountain Porphyry Copper Developments

By FARIS V. BUSH

The copper production of New Mexico is gradually being increased by development of 'porphyry' mines, the latest being the entrance of Phelps, Dodge & Co.'s subsidiary, the Burro Mountain Copper Co., at Tyrone and Leopold, in Grant county. Although the Company has held property in the district for many years, active operations were not commenced until about a year ago, when the driving of the 7000-ft. Niagara haulage tunnel connecting Tyrone and Leopold demonstrated that the syndicate was getting ready for business. Later a railroad was constructed by the El Paso & Southwestern railroad (controlled by Phelps, Dodge & Co.) from Whitewater, New Mexico, on the Santa Fe, west 16 miles, necessitating extensive grading in order to enter the mountains. Following this, an experimental mill and power plant were erected, grading was done for a 100-ton mill several miles east of Tyrone, and active general development in the mines undertaken. The Burro Mountain district is considered as one of the highest grade 'porphyry' copper regions in the United States, the average ore being said to assay 3% and above. Other large companies in the field besides Phelps, Dodge & Co. are the Azure Mining Co., Savannah Copper Co., Mangus Development Co., Big Burros Copper Co., and Woodward Mining Co. There is also a large amount of territory, held by individual owners.

Copper was known to exist in the Burro mountains as early as 1871, but no locations were made, nor were any attempts made to mine it; silver and gold being the only metals to which the prospector turned his attention. Had it not been for the most favorable surface indications, the district would not have been prospected as early as it was. In 1879 the St. Louis mine was discovered by James Bullard, John Swisshelm, and J. W. Fleming, and shipments of surface ores were made to Denver. These gentlemen negotiated a sale with Paschal R. Smith and Frank Marshal, who organized the Val Verde Copper Co. and erected a 50-ton reverberatory furnace in Dead Man's gulch. On account of the high cost of production and a low recovery, they were forced to suspend operations. Later a 500-ft. shaft was sunk on the St. Louis claim, and a large body of sulphide ore was found. During one year 102,534 lb. of copper was shipped from the works. Assays showed the ingots to contain 95% copper, as per returns from the ore-purchasing agency of Pope, Call & Co., of Baltimore. The Val Verde Copper Co. merged with the Southwestern Copper Co., and all operations were suspended on account of marauding Indians. During this time other discoveries were made in the district, among which was the Samson mine, found by George Sublett and Robert Thomson. Theodore Carter got the Leopold brothers of Chicago interested in the St. Louis mine and other properties, in 1901, and organized the Burro

Mountain Copper Co. A 500-ton mill was built at Leopold and treated the ore. The Company made money and was taken over by Phelps, Dodge & Co. in 1904. North and east of the Leopold operations, the Tyrone Development Co. was formed by claim-holders, and this was taken over by the Chemung Copper Co., about 1906. This Company carried on extensive development work, sinking shafts, driving drifts, cross-cutting, and blocking out orebodies. Much of the success of the region can be attributed to this work. The Phelps-Dodge syndicate merged the Chemung property with that previously controlled, bought out a large number of individual claim-holders, and in 1913 commenced the work preliminary to producing.

The ores are essentially the result of secondary concentration of lean sulphides originally formed in an intrusive monzonite mass. Surface indications are ex-

EXPERIMENTAL PLANT AT BURRO MOUNTAIN MINE.

ceedingly favorable for prospecting. The rock in general is exposed, silicified rock with iron and copper stains being found in many places and indicate fracture zones with a northeast-southwest trend. The orebodies in general have a length in a northeast-southwest direction and their shorter diameters lie northwest-southeast. Some dimensions of the bodies are given as follows: 650 by 600 ft.; 450 by 200 ft.; 400 by 260 ft. Development has not proved the thickness of these bodies, all of which contain commercially valuable ore. The only statement given out by the Burro Mountain Copper Co. management was that enough ore had been blocked out to warrant the erection of a 100-ton concentrator.

In order fully to determine the process to be adopted, a 50-ton experimental ore-testing plant was erected near the portal of the Niagara haulage tunnel and the dumps of No. 1 and 2 shafts. This mill has been running since April 1914, but to date the most economic method of separation has not been solved. Two different methods of separation by oil flotation have been tried, but it is declared that to date neither has produced the desired quality of concentrate, and changes of the oily reagents and agitation are still under way. Doubtless flotation will finally be embodied in the flow-sheet of the 1000-ton plant, as the ore is well adapted to it. However, the most economic method may only be found after extensive testing. The Burro Mountain test mill is being closely watched by those interested in mining and milling of chalcocite ores.

The ore-dressing process now being followed in the plant is as follows: From mine to 10 by 20 jaw-crusher, to coarse rolls, and then to dry-ore bin. From here the ore is sized to $\frac{1}{4}$ in. through a trommel, the oversize going to fine rolls and back to the trommel, the undersize going to fine-ore bin. The ore is then classified, the sized ore going to Wilfley table No. 1, coarse to Hardinge conical mill, slime to slime thickener, and thence to flotation unit. The discharge from Hardinge mill goes to classifier No. 2; from here all under 80 mesh goes to the flotation unit, all over is re-ground until it reaches 80 mesh, and then goes to flotation. When the flotation process is not used the ore goes from the Hardinge mill to classifier No. 2, the coarse goes over Wilfley table No. 2, the slime to a spitz classifier; the sand goes over Wilfley table No. 2, and slime to a slime thickener, and then to a vanner. The flow-sheet is being changed from time to time as experiments show it to be desirable. The re-grinding especially is being closely studied. A. Sandburg, of Bisbee, is chief metallurgist, and Henry Stanley is mill superintendent.

Underground development was stopped by the Company at the beginning of the European war, and only enough men are employed in the mines now to keep the test mill supplied with ore from sundry places throughout the property. In future operations the caving system in one of its forms will be used. Practically all ore will be hoisted, both at Tyrone and Leopold, this adding to mining costs. According to the 1913 report of Phelps, Dodge & Co., a body of low-grade sulphide ore averaging 2.35% Cu was opened by drifts in the main haulage tunnel. This ore can be mined at a comparatively low cost.

Three miles east of Tyrone, grading for the large mill has been completed and a town-site laid out. A force of some 30 or 40 men will be engaged all winter in the erection of a machine-shop, carpenter-shop, and crushing building at the millsite, but work on the concentrator proper will not begin until the flow-sheet is settled. A central power plant has been erected at the portal of the 7000-ft. tunnel and near the No. 1 and 2 shafts. It will supply electric power for the operation of mines, mill, and for transportation to mill. The equipment consists of two 1250-hp. (sea-level) Carels type Diesel engines capable of developing 1000 hp. each. Each engine is direct connected to an 815-kva., G. E., 60-cycle, 3-phase alternator. For water supply, mine water is pumped from the No. 2 and No. 3 shafts. It is now being run through several miles of precipitation flumes containing scrap iron. The water is highly charged with copper sulphate, and a high-grade precipitate is sent to the Douglas smelter for treatment. If a larger

water supply is needed, wells at the head of the Mangas 'draw' may be the source of supply. Several churn-drills are at work prospecting new ground owned by the Burro Mountain Copper Co. All construction work and operations in general are under the supervision of E. M. Sawyer.

While the Burro Mountain Copper Co. is the largest operating company in the district, there remains much property of merit, developed and undeveloped, in the mineralized zone, that would warrant investigation. Climatic conditions are such that work may be carried on the year round, the average temperature being about 55°F. Labor is plentiful, the average wages (Mexican) being $2 per day. Transportation costs, which have retarded progress in the Burro mountains, have been lessened owing to the entrance of the El Paso & Southwestern railroad. The cost of copper per pound should not exceed 9c. where development has revealed commercially valuable ore.

Gold Mining in Eastern Asia

Gold is widely distributed over eastern Asia, but the most important deposits are in Siberia and northern China, where in the Lena and Amur basins rich alluvial deposits occur. Those to the north of the Amur are worked by Russians; on the south side the Chinese wash the gravel by methods that are crude but effective. Of recent years the Chinese miners have begun to adopt foreign equipment to some extent, and the illustration at the left of the group picture shows a Chinese miner using a Russian wooden gold pan in Siberia. The Chinese are extremely skillful with the pan, and but little gold remains in ground which they have worked over. Some form of pan is everywhere employed, and the next illustration shows the 'dooling' (pan) and the 'patchule' (hoe) as used in Indo-China. These are the implements of the Malay in gold and tin mining, and, together with bamboo baskets, carrying-poles, and the china pump, constitute practically all the machinery used in the winning of gold and tin in tropical Asia. The prevalence of gold washing in the Amur basin of Siberia may easily give rise to an exaggerated idea as to the importance of these deposits. Generally speaking, except where the use of foreign machinery will permit the working of ground now inaccessible, such as gravel below water-level, or with immensely thick overburden, there is little additional profit to be gained by its use, since the low cost of labor reduces the cost of working by such crude methods to a point where it can scarcely be improved upon. The cost of bringing in foreign equipment is high, and the gradual introduction of native-made equipment following foreign designs seems to be the natural line of progress. The picture to the right of the centre shows Chinese tributers washing ground near an outcrop of quartz veins in Siberia. Note the locked Russian washing machine; also, in the upper left-hand corner, a Russian wooden gold pan such as is shown in the illustration to the left. The top of the machine has a punched screen; only the fine stuff goes through, and the gravel is washed on the screen as shown. The inside of the machine consists of staggered inclined riffles. It does not make as good saving as the rocker. The peculiar shape of the Russian pan does not seem to offer any advantage over the normal conical pan. The Russians who have worked in Alaska have brought back to Asia many of the methods which the Alaska miners have developed, and the picture at the right shows American pattern sluice-boxes, erected in Siberia by a Russian with experience in Alaska. Chinese laborers do the rough work even on the Russian side of the Amur. For these photographs we are indebted to F. L. Cole, who has had extensive experience in China, Siberia, and the Philippine Islands.

THE Dominion Iron & Steel Co., Canada, output last year was as follows: iron ore, 350,000 tons; limestone, 295,000 tons; pig iron, 181,000 tons; steel ingots, 237,500 tons; rails, 120,000 tons; blooms and billets for sale, 23,500 tons; wire rods, 37,700 tons; wire and wire products, 26,000 tons; and steel bars, 15,000 tons.

COPPER CONCENTRATE produced by the Elmore vacuum plant at the Sulitjelma mine, Norway, amounted to 1422 tons in November.

METHODS USED BY CHINESE IN WASHING GOLD-BEARING GRAVEL.

The Rand's Largest Central Power-Station

By V. PICKLES

*The Rosherville plant of the Rand Mines Power Supply Co., Ltd., has a total capacity of about 84,000 kw. It is both an electric generating and an air-compressing station. There are five boiler-houses with eight boilers in each, and a turbine-room 75 by 450 ft. The plant is on Rosherville lake, the largest sheet of water on the Rand, this being the reason for its situation.

Coal Handling.—Coal is delivered along sidings to five outside storage bunkers, one opposite each boiler-house. Underneath the bunker floors are the conveyors, which are fed by rotary fillers through chutes built in the concrete floor of the bunkers. These conveyors are of the Babcock & Wilcox gravity bucket type, and they deliver the coal from the outside to the overhead inside bunkers, whence it is delivered through mild steel plate chutes into the stoker hoppers. Each conveyor is capable of handling 40 tons per hour. Blake-Dennison weighing machines are installed in each conveyor tunnel, which automatically weigh the contents of every four buckets as they pass over the machines. The total reading is taken, and a daily check thus kept on the operation of the station.

Boiler Plant.—The general arrangement of the boiler-houses consists of a basement 10 ft. high, in which the ashes are dealt with. Ash bunkers are provided under each boiler, capable of storing approximately six tons. The ashes are removed in trucks and attached to the haulage gear leading to the ash dump. On the next floor are the boilers themselves, and each boiler unit is of the Babcock & Wilcox marine type, fitted with chain-grate stokers, and each having its own superheater and economizer integral with it. The boilers are arranged in two rows in each house, with a common firing floor. The boilers of the first four houses have a rated capacity of 32,000 lb. of steam per hour, and are capable of evaporating 40,000 lb. of water under favorable conditions. The heating surface of these boilers is 5520 sq. ft.; of the superheater, 1720 sq. ft.; and of the economizer, 2200 sq. ft. In No. 5 boiler-house, which is the most recent addition to the plant, the boilers are slightly larger. The heating surface of the boiler is 5920 sq. ft., of the superheater 2247 sq. ft., and of the economizer 3050 sq. ft. The normal output is 33,000 lb. of steam per hour. The Prat system of induced draft is employed. This system is one found more on the Continent than in England or America. At Rosherville, adjacent boiler units are connected to a common stack, the conical shape of which is probably well known to most of the people on the Rand. Air from an electrically driven fan is forced through the conical part of the stack and thereby produces a suction in the flues and consequent draft through the furnace. The fans for double units are driven by 125-hp., 3-phase, squirrel-cage motors, while those for the single units, that is, the two outside rows of boilers in No. 1 and 5 houses, are driven by a 75-hp. motor. The draft is regulated by means of a damper of torpedo shape moving up and down in the conical end of the blast pipe, and so regulating the volume of air discharged from the fan. The draft can be varied from ½ to 2 in. of water in the uptake. The superheaters and economizers are of the Babcock & Wilcox well known type and need no explanation.

Steam Pipes.—Steam is delivered from each boiler unit to a main open steam-pipe ring in each house. The open ends of this ring are connected by vertical pipes to the main steam header running the whole length of the station. Isolating and section valves are, of course, suitably placed, the main sectionalizing valves being electrically operated. At the bottom of each vertical header steam separators are placed, and the whole range is efficiently drained by steam traps. The main header is anchored at several points along its length, and expansion is taken care of by means of swivel expansion joints, a type not usually found in English practice, but which are fairly well known on the Continent.

Boiler Feed System.—The boiler feed pumps are turbine driven. They are nine in number, and are installed in the turbine-room basement. Each pump is capable of dealing with 280,000 lb. of water per hour, against a working pressure of 225 lb. per sq. in. The turbines are of the simple impulse type with one stage, and are designed for working at 225 lb. of steam at a temperature of 350°C. Regulation is obtained by means of a throttle valve operated by the delivery pressure, and the speed is therefore automatically regulated according to the demand on the pump. The suction of each pump is connected to a feed tank placed inside the boiler-house above the firing floor, and on the delivery side are connected to a breeches pipe, so that they can deliver into either the common or independent feed range. The exhaust steam from the turbines of these pumps is carried to the feed tanks and is exhausted through nozzles directly into the tank, and thus give up practically all the heat of the steam, and the water is also recovered.

Water Purifying Plant.—Water from Rosherville lake is used for 'make-up,' and most of the waters in the reservoirs along the 'reef' consist largely of mine water, and is in consequence quite unsuitable for boiler use without treatment. The treatment is carried out by means of an Archbutt-Deeley softening plant with a capacity of about 8000 gal. per hour. This type of softener appears to be suitable for the treatment of the hard water in the lake. The Archbutt-Deeley plant is hand operated and of the non-filtering type. Chemicals are added, and the water is then allowed to settle

*Abstract of general description for the South African Inst. of Elec. Engineers.

until all the precipitated substances caused by the addition of the chemicals have subsided. The clear water is drawn off from the top by means of a floating discharge pipe into a large reservoir, from which the make-up pumps draw the water.

Turbo-Generators.—Five turbo-generators are installed, each of 12,000-kva. capacity, 50 cycles, and normal voltage of 5000. The turbine is designed for a working pressure of 225 lb. and a steam temperature of 350° C., and consists of the Curtis stage and 12 expansion stages of the Rateau type. The main supply to the turbine enters the nozzle box, which contains 14 nozzles. Four of these are always open, and the remaining 10 are controlled by hand-regulated valves, these being opened or closed according to the load on the turbine. Speed regulation is taken care of by a throttle governor and an emergency trip is provided which cuts off the steam supply at 10% overspeed. Exhaust steam from the condenser auxiliary turbine is delivered to the main turbine at a point between the Curtis and Rateau stages. The generators are bar wound, having one bar per slot. The complete generating unit consists of the generator and the transformer, but provision is made for connecting the transformer for stepping up either to 20,000 or 40,000 volts, as may be desired. Protection of the generating unit embraces both the generator and transformer with intermediate connections. Inverse time-limit overload relays are installed. In the event of a fault developing inside the protection, the unit is immediately isolated by means of the Merz-Price protective gear, and simultaneously the excitation is cut down to almost zero to prevent the fault extending. The neutral point of each generator is earthed through a low resistance. The generator rotors are of the non-salient type, and are 5 ft. 4 in. diameter. They therefore have a peripheral speed of about 278 ft. per second. Ventilation is obtained by means of fans carried at each end of the rotor, the air being drawn from outside through the air filter. Each set contains its own direct-driven exciter, and a standby supply is also provided from a motor-generator and a battery.

Compressors.—The station contains nine steam-driven rotary air-compressors, six of 3000 and three of 7000-kw. capacity, or about 40,000 kw. in all, run at a speed of 3000 r.p.m. These take in air at atmospheric pressure and deliver it into the pipe-line at a pressure of 110 to 120 lb. per sq. in. gage pressure, according to the demand on the system. The smaller sets consist of two stages with an inter-cooler between, and deliver 22,000 cu. ft. of free air per minute with an outlet pressure of nine atmospheres (132.3 lb.) absolute. The larger sets are in three stages separated by two inter-coolers, and deliver 44,000 cu. ft. of air per minute. The stages and the internal diaphragms are water jacketed, with the result that the air is delivered into the pipe-line at a temperature below 100°C., and is cooled during transmission to atmospheric temperature. Each stage contains eight impeller wheels forming the rotor, the air passing through these wheels in series. Between each pair of impellers the air passes through passages in the stator that forms the diffuser when the velocity of the moving air is changed into pressure. The low-pressure end of the larger sets is double ended, the air being taken in at each end, and is discharged from a common duct at the centre. This arrangement automatically balances the end thrust of this stage, but the other stages have to be balanced by special means. The stages are separated from each other by labyrinth glands on the shaft and at the circumference of the impellers, and little leakage takes place between them. The clearance between the grooves and notches of these labyrinths is small, so that any want of balance in the machine would rapidly cause heating of these glands. An automatic non-return valve is provided on the discharge pipe of each machine, and directly the pressure falls below that of the pipe-line the compressor automatically discharges to atmosphere. The low-pressure stage of the steam turbines of the large compressors is also a double-ended device, so as to secure ample area for the steam without unduly lengthening the blades. The condensing plant is similar to that of the turbo-generators, already described.

Switch Gear.—The switch gear is contained in a switch-house at the south end of the building, with cubicles on the outside of the building containing the step-up transformers between the generators and busbars. This building has four floors. The top floor contains the lightning arrester gear and the outgoing lines are fed from this floor. The third floor contains the busbars, both 40,000 and 20,000 volts, and the second floor is the switch floor. The lower floor contains the cableways, etc. The busbars are in duplicate, selecter knife switches being used for connecting to either one set or other of the bars. The 40,000 and 20,000-volt systems are connected together through a coupling transformer of 10,000-kva. capacity. The switches themselves are three single-phase coupled switches, and are operated from the control board. This control board is placed at the south end and overlooks the whole of the engine-room. A large signaling board is placed in such a position that it can be seen at any point of the engine-room, and from which instructions can be signaled to the drivers of either the turbo-generators or compressors.

POTASH SALTS imported into the United States in December were as follows:

	Quantity.		Value.	
Classes.	1913.	1914.	1913.	1914.
Carbonate, pounds	2,350,853	1,362,138	$75,990	$56,169
Cyanide, pounds	213,177	11,200	28,271	2,118
Hydrate, pounds	1,303,359	1,630,468	50,494	65,465
Nitrate, pounds	560,000	.....	19,448	.....
Muriate, tons	28,619	8,313	932,599	311,011
Sulphate, tons	6,459	2,204	271,585	101,542
Other salts, pounds	695,373	503,349	63,957	52,167

CONSTRUCTION of the Trans-Australian railroad, 1060 miles, by the Commonwealth government, continues. On December 19 there was 308 miles of track laid and 2070 men employed.

DISCUSSION

Readers of the MINING PRESS *are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.*

Dissolution of Silver and Gold in Thickeners

The Editor:

Sir—I beg leave to correct one statement in Mr. Menier's letter on Oliver filters at the Commonwealth mill, Pearce, Arizona. He states that the dissolution of metals from the pulp during its passage through the four 40 by 12-ft. Dorr thickeners is *nil*.

I will explain that the slime-pulp, after treatment in the nine Pachuca agitators, is diluted with barren solution 3 to 1, thickened 1.5 to 1, and transferred by 4-in. air-lifts through the four thickeners in series before the final caking to 28% moisture. The thickeners are arranged for counter-current replacement. The four filters are 11.5 by 16 feet.

No further extraction is gained during filtration, but the following assays for the month of September 1914 show an average extraction of 0.33 oz. silver:

September	Agitator tailing, oz.	Oliver tailing, oz.	Silver dissolved, oz.
1	1.73	1.44	0.29
2	1.68	1.50	0.18
3	1.84	1.60	0.24
4	2.14	1.66	0.48

FREDERICK A. VOORHEES.

Pearce, Arizona, January 14.

Who Will Engineer the Engineers?

The Editor:

Sir—Among the many interesting subjects covered in the 'Discussion' columns there is one which to me and to others, perhaps, has seemed to be neglected. It is with this idea in mind that I am tempted to precipitate a discussion of the question as to just why members of a body which has always been given the title of a profession should find themselves in the position in which the majority of them are today.

As a freshman in a reputable college of mining engineering, some twelve years back, I was given to understand that immediately after graduation I could expect to put in some years at hard labor, learning the practical side of mining, and serving what, in anything like a trade, would be called my apprenticeship. After a term of years I was led to believe that my diligence and industry, as in all the fairy tales, would be rewarded by a life whose requirements would vary between being the guide, philosopher, and friend of the trusting capitalist and the free-and-easy associate of the wily burro and his friend, the prospector—in other words, a sort of elastic nature, who could be all things to all men—who would be as needful of a dress suit in his wardrobe as a pair of overalls. In fact, I rather expected to be wearing these garments on alternate days, with all the associations that their possession implies.

Fond illusions! The dress suit is now moth-eaten, but the overalls have been replaced many times. In fact, if the war had not interfered, the price of cotton might, in time, have made even these humble garments beyond the average E.M.'s means. Whatever may be the cause of the downward trend in engineering salaries, the fact remains that the average member of the engineering force of any of our larger mines, in a position of some trust and no little responsibility, averages rather less in his monthly pay-check than the ordinary ten-day miner who has to be guarded on every turn to keep him from 'high-grading' the profits away from the mine.

In saying this, the intention is far from that of striking a personal note. My own case has perhaps been rather more fortunate than that of many of my fellows, in that I have at least had the satisfaction of having held a few good positions, while they lasted, and in having the more or less immediate prospect of holding more. This has perhaps been on account of not being married, and being able to handle examinations in the more remote parts of the world. But the average mining engineer who marries and does not give up his pro-

fession usually ties a millstone around his neck. This is a strong statement, but true, and explains why some eighty per cent of my own class in college have given up mining, and among them have been men of exceptional capacity. They could see the cold fact with clear vision—that the years of their youth would be wasted on the petty details of a subordinate position which they dare not give up on account of the responsibility of a family—and when they grew older, or the mine played out, they would be turned adrift. Would they not have been foolish to stay with their profession? Some few, however, have stayed, and as the years go by the story will be told.

Why is it, then, that a profession, and surely it is entitled to the name, that demands more of self-reliance, more of ingenuity and individuality, as well as more of dogged hard application and work, than any other that one can name, commands no more respect at the hands of the mining interests of this country? Let us examine some of the causes.

First, the law of supply and demand. For the last eight years, at least, mining has been on the wane. Capital has been timid of investment, and many of the older mines have curtailed their operations and their staffs. Mexico has driven out many experienced engineers. On the other hand, our technical schools have been grinding out graduates with marvelous energy. These are often in competition with older men, and sometimes make good over them. With this there is no quarrel, as no one seeks to interfere with the principle of the survival of the fittest. But, on the other hand, is it not the fact that the very necessity of training inexperienced men holds down the initial salaries, and thereby lowers the status of the experienced efficient man who is forced by circumstances to seek a new job?

It seems to me, and I find that my opinion is concurred in by many others of my fellows, that some sort of an organized effort to change the general situation would be effectual. Personally, I am able to speak from the standpoint of the operator, the superintendent, the engineer, and the 'mucker.' I know that in keeping down costs, I have at times taken advantage of the surplusage of engineering talent. Nevertheless, I did it with a protest against the conditions which forced me to do it, and I have often pondered, in my own mind, as to whether the situation could not be alleviated, to some degree at least.

There can be no question in the minds of any that an efficient man in a position of responsibility often has chances to save many times his monthly pay check—at least in a mine of any size. There can equally be no question that among the horde of engineers, now fortunately diminishing, that is being turned out of technical schools every year, by graduation and other more expeditious methods, there are many men who fortuitously attain to positions which they are not fitted either by training or experience to hold, and which, if they do hold them, are caused to suffer from inexperience for some months, if not years. If a man has a pleasant personality and a disposition to make good, there are few superintendents or managers who will not overlook all but the most glaring errors. The cost of these errors is usually charged up to the general salary account—in other words, the engineering staff as a whole in that and other mines, pays for the experience which the novice, or the man who is trying to make a bluff stick, is getting in competition with them.

This being the case, and I think many operators and managers, as well as engineers who have been long in the field, will agree with me that it is, does it not seem as if, by means of the college engineering associations or some more general bureau, a register of engineers could be started whereby the individual record of each engineer at actual work in the engineering field could be kept for reference? This record should be entirely independent of the college record, except along general lines of training, for many who graduated by accident know full well that there were better and abler men who failed of getting their diplomas.

The idea would be, in general, to have some definite and responsible bureau to whom managers, operators, and superintendents in need of competent engineers could apply and be sure of getting a man whose experience and training, as well as personal record, exactly fitted him for the work in view. Having once established such a bureau, I should go one step farther. It should be the duty of the secretary, or whatever else he might be called, to safeguard the interests of the engineer as well as the employer, and send no man out to a position of responsibility unless he were paid what he was worth. While this might seem arbitrary, and to savor of the walking delegate, I think that the satisfaction of being sure of getting a thoroughly competent man, who would not require more than two or three days' education in his new duties, would be worth much more, financially and mentally, to the average manager and operator, than the difference in salary.

An association of this sort could be financed with only a trifling expenditure on the part of each engineer registered. Of course, many difficulties would be encountered, in the way of disgruntled inefficients. These would soon automatically eliminate themselves, and the engineering field would be the clearer and better for it. The responsibility of passing on the qualifications of a man should be left to the superintendent himself, after a study of the records of several candidates submitted.

Personally, I think the details of such a plan are not impossible of working out. Not having the time to do so, and not flattering myself with the possession of omniscience, I should like to see the idea thoroughly discussed, and other better ideas brought forth; and if thereby I shall have started something which will trend toward the general betterment of the present ridiculously low average of engineering salaries, and at the same time toward raising the standard of general efficiency, a great good will be effected.

A. ENGINEER.

San Francisco, January 20.

CONCENTRATES

Readers of the MINING PRESS *are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.*

THE St. John del Rey mine, Brazil, has a vertical depth of 5711 ft., and is the deepest metal mine in the world.

STICHTITE, named after Robert Sticht, of the Mount Lyell mine, Tasmania, and previously known as 'kammerite,' is a carbonate-hydrate of magnesium, chrome, and iron.

"A HUNDRED DOLLARS IS SPENT on the prevention of accidents in the anthracite coal regions of Pennsylvania," said a prominent operator recently, "for every dollar that is spent on their cure."

GOOD GRANITE should stand a crushing strain of at least 20,000 lb. per sq. in.; some granites will stand 40,000 lb. This may be compared to common red brick, which will crush at about 3000 lb. pressure.

THE FILING OF AFFIDAVITS as to annual labor on mining claims only constitutes *prima facie* evidence that the work has been done, and may be rebutted by competent testimony as to the actual facts. If no work has been done in a tunnel for three years, all rights under the tunnel-site location have lapsed, and if no assessment work has been done on the claims tapped by the tunnel, they as well as the tunnel site are open to location.

THE CALORIFIC VALUE of a fuel is the total quantity of heat developed by the complete combustion of the unit weight of fuel. In the metric system of measurement, which is generally used by chemists and physicists, the heat units are the 'gram calorie' and the 'kilogram calorie.' The gram calorie, or small calorie (cal.) is the amount of heat required to raise the temperature of 1 gm. of water 1°C. at 15°C., and the kilogram calorie, or large calorie (Cal.) is the amount of heat required to raise the temperature of 1 kg. of water 1°C. at 15°C. In the English system, which is generally used by engineers, the heat unit is the 'British thermal unit,' or B.t.u. The British thermal unit is the quantity of heat required to raise the temperature of 1 lb. of water 1°F. at 60°F. Calorific values given in calories per gram may be converted into British thermal units per pound by multiplying by 1.8, the ratio between the centigrade and Fahrenheit degree. The factor for converting grams to pounds does not enter into consideration, as the heat developed by combustion of a unit weight of fuel is always measured by the rise in temperature that it produces in an equal weight of water.

A MINER holds by location two claims with no vein outcropping, and a tunnel site, on which no work has been done. A good deal of rich 'float' quartz is scattered over the area. Will the tunnel site hold all 'blind' veins that it cuts, even though they extend into another property but do not outcrop there? How much work must be done on a tunnel site to hold the same? And would this work act as assessment work on the claims that the tunnel site is located on? Work must be done in the tunnel with reasonable diligence, in order to protect the claim to blind lodes cut by the same. Cessation for six months will cause the claim to lapse. A person cannot acquire title through a tunnel location to blind lodes in valid mining claims owned by others, and can not get an extralateral right on blind lodes in his claims until he is in a position to prove the existence, course, and extent of the apex in such claims. Assessment work, as the term is ordinarily used, is not required for a tunnel site; but of course work done in the tunnel for the development of claims located over it could be counted as assessment work on such claims. What is required for the validation of a tunnel location is continuous development work in the tunnel, without cessation for a greater period than six months.

COST OF CYANIDE TREATMENT is liable to vary within wide limits and is influenced by a number of factors. Cyanide and alkali consumption will depend on the character and cleanness of the ore being treated; and other chemicals, such as lead acetate or bromo-cyanide, may be found necessary to aid extraction. The proportion and distribution of base metal present will also affect the cost of treatment, involving in some cases the expense of concentration and in others the additional cost of shipping the concentrate produced. Roasting may be imperative as a preliminary to cyanide treatment. The output from the crushing and regrinding machinery is limited by the hardness and toughness of the ore; and the treatment cost per ton is influenced by the judgment shown in the selection of proved units for every department. Certain items of cost are only slightly affected by a variation in the amount of ore handled, so that the cost per ton will materially decrease with higher tonnages. The installation of labor-saving devices and smooth-running machinery will insure lower costs both for running and repairs; and the presence of favorable local conditions may result in good profits where losses might otherwise result. Difficult transportation and high freight costs make considerable differences in profit estimations, but sometimes this is counterbalanced by cheap power. Pebbles for tube-milling may cost anywhere up to $60 per ton, or may be made locally for a tenth of this amount. Royalties on various patents are paid in some localities and evaded in others.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

ROCHESTER, NEVADA

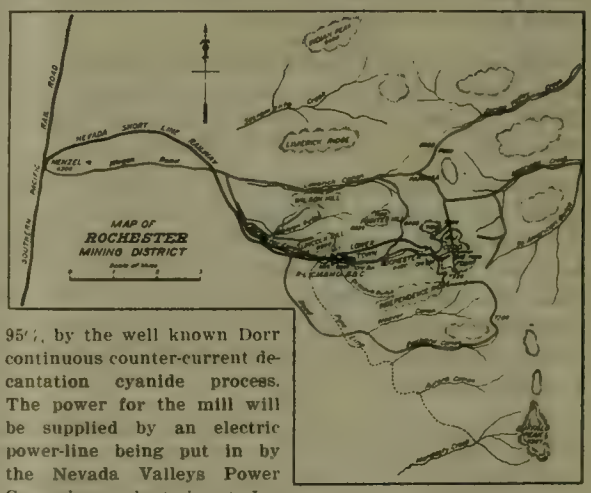
HISTORY AND PROSPECTS OF THIS NEW DISTRICT.—THE RAILWAY, SMALL MILL, AND NEW MILL.—NENZEL HILL MINES.—LIMERICK RIDGE, WILSON AND LINCOLN HILLS.—GOLD-SILVER ORES OF INDEPENDENCE RIDGE.

Rochester begins to look like a real mining camp with its large bodies of ore blocked out, a railroad right into town, one small mill turning out bullion, and a large custom mill almost ready to start, besides other mills proposed for the near future. The district is a little over two years old, and has quite a remarkable record as far as mining is concerned, in that it has been practically self-supporting. During its first year ore shipments amounted to an aggregate of over $500,000. It was not high grade, but the short haul to the railroad made it possible to ship $25 ore at a profit, this being the average value of the 550 cars of ore shipped during 1913. This close proximity of the railroad was in many ways a serious detriment to the mining end of the camp. It enabled the rabble and the hobo to get into the place. It resulted in a great townsite boom, wherein much money was lost that could have been spent in development to the betterment of the district, and to the personal profit of these people, who, as it was, lost their money and went away from Rochester with anything but good words for the place. Gambling was 'wide open' and the 'suckers' were cleaned. More saloons were opened than would supply the wants of the two or three largest cities of the state. Business houses of all sorts were so numerous that they could not help but fail. All these losses were entirely independent of mining, but they assisted in building up a fake boom which eventually reacted against the mining industry. But during all this time the legitimate prospector, and particularly the lessee, were quietly extracting ore and shipping it, and using the profits from one shipment to open more ore. As soon as a custom mill seemed to be assured, many of the lessees quit work to wait for the mill, while others stopped their shipments but kept on developing ore, with the result that today there is enough ore blocked out in the different mines to keep the new mill running at full capacity for over two years. And as this ore runs from $10 to $25 per ton, there will be a good profit realized from these reserves.

The Nevada Short Line railway, better known as the Codd road, is completed from Nenzel, formerly Oreana, on the 'Espee' (Southern Pacific) to the Lower Town. The road from the mill to the upper part of the district has been surveyed, and construction will be started as soon as the frost is out of the ground. In the meantime the ore will be hauled from the ore-bin at the end of the tramway to the new mill by teams. The mill is nearly finished, and is expected to be running about February 7. The railroad has just started a new gasoline motor passenger car. This car was built at Reno, and its trial runs have been satisfactory. The car seats 12 passengers and carries a little baggage, express, and mail. It makes the run from Nenzel to Rochester in about 30 minutes, climbing from 4200 to 5800 ft. elevation. The car makes two trips per day, meeting both trains on the main line.

The small mill is a two-stamp Joshua Hendy amalgamation plant, owned by the Lincoln Hill Mining & Milling Co. It is situated in Rochester cañon, just below the mouth of Octopus gulch. The power is obtained from a gasoline engine, which also runs an electric generator. The water is pumped from a well in the bottom of the creek bed, from which a drift was driven on bedrock across the whole channel to develop all the water possible. This Company owns two claims on the north slope of Lincoln hill, from which it is mining gold ore, some of which runs as high as $300 per ton. A few lots of ore for lessees on Lincoln and Wilson hills have been crushed, the last lot being from the Gotham claim on Wilson hill, owned by U. W. Harwood, and which returned $67 per ton.

The new mill being built near the lower part of Rochester cañon is about opposite Octopus gulch. This mill is guaranteed to treat 100 tons per day, and to make an extraction of



95%, by the well known Dorr continuous counter-current decantation cyanide process. The power for the mill will be supplied by an electric power-line being put in by the Nevada Valleys Power Co., whose plant is at Lahontan. The water for the mill is brought by gravity from a small stream about six miles southeast.

Nenzel hill has had the most development work done. Here are three leasing companies working on adjoining blocks of ground. They are all opened to the same level, which is about 500 ft. deep on the dip of the vein. Large quantities of ore have been shipped from these leases, and a good tonnage of milling ore is blocked out in them, waiting for the mill to start. A new adit has been driven at about the middle of the properties as a working exit for them all. A surface gravity tramway is being constructed from this about 1000 ft. long to ore-bins at what will probably be the terminus of the railroad.

Silver was the predominant metal in the ore on Nenzel hill near the surface, while on the lower level there is quite an increase in the gold content.

About two miles to the south of Nenzel hill is the Packard portion of the district, from which the richest silver ore has been shipped, and in the past three months production was $45,000.

Limerick ridge, Wilson hill, and Lincoln hill have two systems of veins; those running nearly east and west are being prospected more thoroughly at the present time, containing almost free gold ore. The cross-veins run about southwest and contain considerable silver, but so little work has been done that not much is known of these veins. H. C.

Potter has recently taken a lease on part of the Nonpareil claim where both systems of veins are found and purposes to drive an adit to open the veins at their intersections. His ground is situated on the north slope of Lincoln hill, pretty well down near Golden gulch, where he will have good backs. Some fine specimens of free gold in white quartz have come from this part of Lincoln hill. In the upper part of Limerick canon there are several miners working placer claims in bedrock drifts, 30 or 40 ft. below the surface. Some of the gravel is worked in dry-washers, while the balance is taken about a mile down the cañon to a spring and washed.

Just across Octopus gulch, on the southern extension of the Buck & Charley vein, the Rochester-Lincoln Consolidated Mines Co. is opening a vein in two adits. Some ore has been shipped from the upper one, and the lower is showing ore in two places.

Just to the east of the latter property are the Octopus claims, on which considerable work has been done. Nothing has been shipped from this property, but ore of good milling value is being opened.

Independence ridge shows the ore to contain about equal amounts of gold and silver. The Buck & Charley mine has been the most developed, and is one of the promising mines of the camp. Six men are working it under lease, and have shipped considerable ore, sending out about two carloads per month; but now that the railroad has laid a spur track to their ore-bin, they expect to increase their shipments to five cars. The ore averages about $40, although some of their shipments have run up to nearly $100 per ton. This is the first mine in the district to be connected direct with the railroad.

WASHINGTON, D. C.

Leasing Bill Amendment.—Radium Production.—Mining Legislation.

A matter of importance in mining legislation in Congress is the action by the committee on public lands of the Senate in so amending the so-called leasing bill in the conservation program as to exclude from its operation coal and potash lands. The committee decided to amend the bill in a minor manner. In other respects it is as it came from the House, and that bill will still, in its leasing provisions, apply to oil, gas, and phosphate lands. It is the plan to report separate leasing bills for the coal and potash lands, which may be introduced at this or the next session of Congress. Such is the report of the committee, and it is declared that by modifying the leasing bill in this manner a great deal of opposition to the bill has been removed, so that the bill in the Senate has less opposition than any of the conservation measures. The prospects of passing the bill are known to be small, in view of the filibuster in the Senate against the ship purchase bill which has so far blocked all legislation. Even should the filibuster be raised soon, it is thought all other legislation would be prevented enactment, except the supply bills and other minor measures to which there is no opposition in Congress.

The House has had under its immediate inspection some of the radium which has been produced from Colorado fields, the total amounting to $10,000 in value, and being shown in the House by Martin D. Foster, from Illinois, chairman of the House mining committee, to demonstrate what this country could do in radium mining, and especially the Bureau of Mines, which treated the ore by processes of its own at Denver, and at such a reduction in cost that radium heretofore available at $120,000 per gram ought to be salable at $40,000. The Bureau is to make public its processes at a later date. The radium was the property of Howard E. Kelly, of the Johns Hopkins hospital at Baltimore, Maryland, and of James Douglas, who operates a large cancer institution in the city of New York. These gentlemen supplied the radium from lands owned by them in the West, and it was treated by the chemists of the Bureau at Denver. The cost was defrayed by the United States government out of the annual appropriation of $100,000 for experiments in the treatment of ores. After the gentlemen named shall have obtained seven grams of radium, the radium fields they own are to become the property of the United States, and it is believed that enough radium will be acquired by the government to equal in value the $100,000 appropriated for experimental purposes. The presentation of the radium in Washington was attended by a banquet at which many felicitations were expressed. Mr. Kelly and Mr. Douglas declared their faith anew in the therapeutic value of radium, saying that what cancer cures have failed from the application of radium were not due to the use of radium, but to the fact that the cases were such that there was not enough radium on hand to effect the cure. Of course, radium legislation is being held up among others in Congress, and for reasons apart from the filibuster.

All other mining legislation broached in Congress also remains in a dead-still position. It is hard to prophesy what will happen in the remaining month of the short session of Congress, but of course, if there is to be an extra session, many of the things the mining people are asking for may receive attention, providing they do not involve any large sum of money, as the government is short of funds, revenue being far below the expenditure, and so it is loath to undertake anything new carrying an appropriation.

DEADWOOD, SOUTH DAKOTA

Snowfall.—Homestake Company's Activities.—Oro Hondo, Echo, Golden Reward, and Hidden Treasure Mines.

A fall of 16 to 20 in. of snow, as measured at various points in Lawrence county, on January 17 and 18, makes the record for the present winter. Having been favored with an especially fine season to date, operators were well prepared for the storm, and no distress has been reported among them. The Wasp No. 2 company stopped work in the open-cut workings, from which the entire mill supply is drawn, and will not resume for some weeks. This action follows the usual custom at this property, namely, to suspend during the severest of the winter. Other properties are running full time.

At the Panama-Pacific Exposition the Homestake Mining Co. will make a highly instructive and interesting exhibit in the Palace of Mines and Metallurgy. It will include a reproduction of a portion of the mine, showing stopes, shafts, and methods of mining. There will also be a complete selection of rocks and ore and wall materials from vairous parts of the great property. Another feature will be a collection of photographs, interior and exterior, of surface plants, and a great number of underground views. The exhibit will be the most complete ever arranged by the Company, and will be carefully installed so that all conditions at the property may be readily understood. The various items entering into the exhibit have been shipped to San Francisco, and A. J. M. Ross, of Lead, of the engineering force of the Company, has left for that point to install the exhibit and remain with it during the Exposition. ——Under the laws of the state of South Dakota, the inheritance tax on the estate of T. J. Grier, late manager of the Homestake company, was $3398, on an estate appraised at $243,000. The tax was recently paid to the probate court of Lawrence county.——During 1914 the Homestake company's employees' aid fund disbursed in benefits the following sums: death, $12,400; injury, $9054; sickness, $10,606; and one suicide, $200. Receipts during the year were from employees, $28,017; from the Company, $12,000; interest, $952. Cash on hand December 31, 1913, was $30,035, and at the end of 1914 the balance was $38,543. The fund is supported by the men and the Company. Each employee gives $1 per month, and the Company provides $1000 per month. Benefits range from $1000 for accidental death or total disability through accident, to $1

per day for sickness or injury causing loss of work. In this connection it might be mentioned that the Company provides free medical service for all employees and their families, this service including medicines and hospital care if necessary. A large new hospital is to be built during the present year, to cost about $25,000.——Construction work on the new headframe at the B. & M. shaft of the Homestake is proceeding at a good rate, and the great steel structure will soon be completed. The engine room has been enclosed and the work of setting up the Nordberg hoist is well under way. At the electric plant, near the Amicus mill, machinery is being erected, the building being complete. The boiler plant, which will furnish steam to operate the two above-mentioned installations, is making good progress. Nearly all brickwork is done, and the roof will soon be finished.

With the completion of a station now being cut at the 1400-ft. level in the Oro Hondo shaft, the auxiliary hoisting engine will be removed from the 1000-ft. level to the new station, and sinking resumed. A small amount of water is being encountered below 1000 ft., and this is easily handled by sinking pumps. From the dam on the latter level, water is hoisted to the surface in the skips operated by the main hoist. Considerable water is handled from this point, as on this level are nearly 3000 ft. of lateral workings.

Shaft sinking has commenced at the Echo property, in the Maitland district, starting from the surface. The equipment includes a 22-hp. Vulcan single-drum hoist, driven by electric motor; an 8 by 8-in. Bury single-stage belt-driven compressor, operated by electric motor; two Western air-hammer sinking-drills; a Shaw drill-sharpener; and a swing cut-off saw in the timber-framing shed. Everything about the plant is running smoothly, and good progress may be anticipated in sinking the several hundred feet the Company proposes to do.

With the addition of 60 stamps to the Golden Reward mill, at Deadwood, the plant will be practically doubled in capacity. The stamps being used are those purchased at the old Hidden Fortune mill, which the Company took over last summer. Treatment of the Company's 'blue' ores, by roasting and fine grinding prior to cyaniding, is yielding good results, and the Company hopes to make the present one of its banner years in point of gold production.

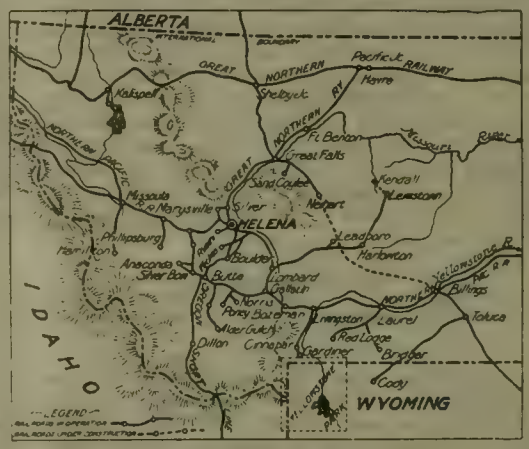
Shaft sinking is under way at the Hidden Treasure property in upper Deadwood gulch, and the shaft, which was 210 ft. deep when unwatered, is rapidly being deepened with the aid of air-drills. The formation is phonolite and porphyry, cut by numerous lenses of ore carrying a large amount of fluorite. S. R. Thompson, of Deadwood, is superintendent.

HELENA, MONTANA

HISTORY OF THE HELENA DISTRICT.—WORK OF THE HELENA MINING BUREAU.—DISTRICTS AND MINES.

Ever since 1893 the mining industry in the Helena mining region has been in a quiescent state. Up to that time Helena was one of the best known mining centres in the West, and work was progressing rapidly and satisfactorily in the adjacent mining districts of Rimini, Unionville, Lump Gulch, Marysville, Corbin, Wickes, Montana City, and others. Various causes contributed to the closing of a large number of these mines, and owing to local financial difficulties many of them were not reopened for several years. In the meantime the miners and prospectors of the region went elsewhere. After their departure, prospecting in the hills and valleys was continued in a desultory manner, and several efforts, more or less successful, to secure the enlistment of capital, were made without any continued specific results being obtained. The latest movement in this direction is in the hands of the Helena Mining Bureau, Inc., which was organized and incorporated through the Helena Commercial Club for the purpose of conducting a campaign for the revival of the mining industry for a minimum period of three years. The Bureau was incorporated for $100,000 at a par value of $5 per share, the minimum subscription received being for thirty-six shares, payable one share per month.

The working plan proposed and adopted was to take over a property within a radius of 10 miles of Helena, and to develop it; if it showed promise, to turn it over to a larger aggregation of capital at a reasonable advance over its cost to the Bureau. Two hundred and eighty-two individuals of the business and professional classes subscribed for the stock, giving the Bureau a monthly income of $1500. Forty-nine properties were offered to the Bureau and carefully examined by responsible mining engineers. Two of these were leased and bonded, and work started immediately. One property consists of three claims known as the Wayside group, situated in the Scratch Gravel hills, six miles from Helena; the other, known as the Hawkeye mine, is within the city limits. The Bureau equipped both properties with machinery good for 500 ft. depth. The work is conducted under the supervision of a board of seven directors chosen from the responsible



MAP OF MONTANA.

business men of the city, who give their time and work free of cost to the Bureau. The results so far obtained in both properties are very gratifying to all concerned, tending to increase the confidence of local people in their mining resources.

Outside of the 10-mile district, the Bureau receives listings of various properties in which investment can be made, and which are all open to full examination by mining men. *Bulletin* 527 of the U. S. Geological Survey gives a full description of what is known as the Helena mining region. The data for this bulletin were compiled under the direction of Walter Harvey Weed. On the invitation of the Bureau, Mr. Weed came to Helena and made a detailed examination of the country within the 10-mile radius, and conclusions summed up in his report are to the effect that the Helena area presents great opportunities worthy of investigation and development by large capital.

The work of the Bureau has had a most remarkable influence in this district. Owners of properties lying idle for some years have resumed work. Prospectors have been active and in the whole district there have been more men working than for many years past. In addition, outside mining men are coming in, making purchases and preparations for developing them. In the Bald Butte and Marysville districts the older mines are being reopened, and new organizations perfected. The Shannon, Cruse, Bald Butte, and Piegan-Gloster are working and planning for larger development. The famous old Drumlummon and St. Louis properties, after a stormy career in the courts, running over some 22 years, are

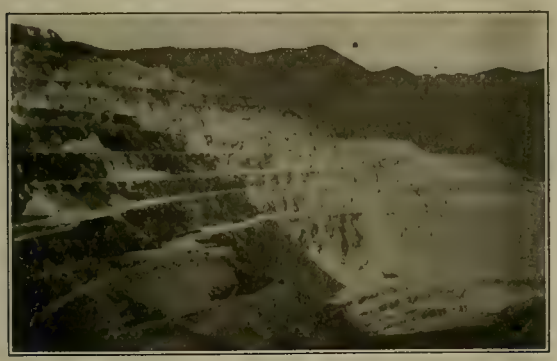
approaching a point where responsible parties will take hold of them.

In the Rimini district, James Breen has installed the first unit of a 500-ton stamp-mill for working the great porphyry dike. The Valley Forge, which opened good ore last fall, is working continuously. The Lee Mountain and other large properties there will be working steadily by spring.——In the Unionville district there is also great activity, a number of Butte men having secured ground with a splendid past record and with which they are entirely satisfied. The old Whitlatch Union and the Spring Hill properties, both of which are acknowledged to be of excellent promise, will be actively worked within the next few months by ample capital.——Several discoveries have been made in the Montana City and Jackson Creek districts, on which work is being actively conducted.——The Franklin mine, in the Scratch Gravel hills, four miles from Helena, owned by the estate of Thomas Cruse, the original locator of the Drumlummon, has been shipping a high grade of steel galena for the past year, and still continues to do so. The mine is also shipping high-grade free-milling gold ore from a cross lead on the same property.—— The York Mining Co., at York, north of the Missouri river, took over the old Little Dandy property last year. The Company installed a large mill and the results reported are very gratifying.

NEW YORK

Dividends Paid by Mining Companies.—Railways and Rivers of Alaska.—Utah Copper Mill Improvements.

Total dividends paid by 120 mining companies in the United States during 1914 amounted to $96,820,912, according to compilations made by one of the brokerage houses. This does not include some of the largest copper companies, and the same



SOME OF THE UTAH COPPER CO.'S WORKINGS.

authority states that if these companies were included, the total would exceed the dividend disbursements of all the railways in the United States for the same period. The average yield to stockholders was 18%, not including any profit due to increase in the selling price of the stock.

Both the Copper River & Northwestern and the Alaska Northern railroads have been offered for sale to the United States government, which is now authorized to own and operate railroads in the territory. The Copper River road with its terminus at Cordova, cost $25,000,000 for its 196 miles of line. The Company has $50,000,000 stock. The Alaska Northern has issued only $5,000,000 of the $30,000,000 of stock and bonds authorized. The government has provided $35,000,000 to be expended for its railroad. Franklin K. Lane has stated that surveys have been made for other lines up the Copper and Susitna River valleys, respectively, which would obviate the necessity of buying either line. The Coast and Geodetic Survey has discovered a channel through the delta of the Kuskokwim river and the shipping lines from Seattle have announced sailings to the Kuskokwim at the opening of navigation in the spring. The Kuskokwim is, next to the Yukon, the largest river of Alaska, but although it is 9 miles wide at its mouth and navigable for 600 miles inland, the flats and bars of its delta have until now effectively barred the entrance of steamers. The opening of a channel will aid greatly in the development of this part of Alaska, which has been held back by its inaccessibility.

As a result of the introduction of the flotation process at the mills of the Utah Copper Co. the Magna will be increased from 12 to 18, and the Arthur from 9 to 12 units. This will increase the capacity of these plants from their present 20,000 to 30,000 tons per day. For the agitators to be used, an ingenious mechanical improvement has been made, in that instead of being driven by belts, the propellers are placed on the extension of the shaft of a suspended 10-hp. motor. It has been computed that the cost of the copper recovered by flotation will be 4½c. per pound. This, of course, does not include a proportionate part of the preceding work done on the ore; but merely represents the cost of saving copper which would otherwise be lost in the tailing. The increase in the output resulting from the greater saving will bring the total production of the Utah Copper up to 200,000,000 lb. annually. Some time ago the Utah metallurgists made an ingenious improvement by re-concentrating the concentrate from the concentrate; equivalent to a reduction of $1 per ton in smelting charges.

A seat on the Stock Exchange was transferred for $40,000 on January 28. This is $2000 above the last sale.

TORONTO, ONTARIO

Power Shortage at Cobalt Resulting in Curtailment of Operations.—La Rose, Nipissing, Temiskaming, Crown Reserve, and Tough-Oakes Mines.

The output of the Cobalt silver mines will be considerably curtailed during the next three months or more on account of the shortage of power. Owing to the light rainfall last year, the Northern Ontario Light & Power Co. finds that it is unable to deliver the power required for operating the mines at capacity. Arrangements have consequently been effected under which every mill is to be closed down for one week in every four. Under normal conditions, the Company has a capacity of 17,000 hp., but with the present low water the greatest available volume of power is 10,200 hp., of which the mills alone require 5000 hp. The decrease went into effect on January 25, causing the laying off of about 300 men. Some of the mining companies will shut down for three weeks at a time, so as to have only one stoppage, and others will close for a week every month. Mining operations will in many cases be continued with power from auxiliary steam plants.

The quarterly report of the La Rose Consolidated ended December 31, 1914, shows a reduction of the total surplus, which amounts to $1,214,400, compared with $1,396,619 for the previous quarter.——The financial statement of the Nipissing, as of January 2, shows a surplus of $1,396,778, of which $437,524 was cash.——The recent discovery on the Temiskaming is proving to be of considerable importance. The vein which came in from the Beaver on the 530-ft. level has been followed 40 ft., and is still good in the face, and 5 in. wide, forming one of the longest ore-shoots so far found on the property. It has yielded 9 tons of ore.——The annual report of the Crown Reserve will show a decrease in production of about 250,000 oz.——The power-plant of the Meteor mine, which adjoins the McKinley-Darragh, was completely destroyed by fire on January 15.——At the Tough-Oakes, the mill is nearly ready for operation, all that remains to be done being the adjustment of some parts of the machinery. The first treatment of ore is expected in March. There is about 7000 tons of ore on the dump. Active underground work has been resumed, and 13 faces can supply ore.

THE MINING SUMMARY

The news of the week as told by our special correspondents and reflected by the local press.

ALASKA

Cordova

A shipment of 250 tons of copper ore from the Mother Lode mine left Cordova by the *Mariposa* on January 16. The total to date is 391 tons, averaging $160 per ton. Another lot will be sent out in February, and the superintendent, J. J. Godfrey, expects to ship about 1500 tons this winter. A Leschen aerial tram carries ore to McCarthy Creek flats, and there is a sled haul of 14 miles to the railway. The property was fully equipped last summer. There are 40 men employed.

Fairbanks

Quartz miners at Fairbanks are busy. The Rhoads-Hall company employs 24 men, and the mill crushes 17 to 20 tons

RHOADS-HALL MINE AND MILL, FAIRBANKS.

per day. Crites and Feldman are extracting good ore. C. E. Hellig is preparing his mill for custom work. The Chatham mill recently crushed 100 tons for McNeil. The Newsboy company hopes to develop ore in its 100-ft. drift.

Iditarod

Gold valued at about $250,000, the property of the Yukon Gold Co., was hauled from Iditarod to Tanana by J. M. Haley and partner with a dog-team on December 29. The gold was delivered to the stage for shipment to Chitina and the 'outside.' Mails to Iditarod are going in from Seward. Mining is quiet in the lower river areas, but miners are optimistic.

Juneau

The federal mining inspector, Sumner S. Smith, will probably ask the territorial legislature to amend the mine inspection law passed at Juneau two years ago, giving him full power to enforce the regulations. The law states that the territorial inspector shall work under the direction of the federal mining inspector, but it fails to give the latter jurisdiction in seeing that the law is upheld. Mr. Smith has started classes of instruction in pulmotors and helmets at Treadwell.

In the application of the Matanuska Coal Mining & Development Co. for title to 1290 acres of coal land in the Matanuska district, the land department at Juneau has refused to grant it. The government stated that the locators did not make preparations for mining coal, which the Company admitted, but claimed that work done three years ago entitled them to the title under the Alaska Coal Land act of 1904.

In the Sheep Creek power suit of the Alaska Gastineau and Alaska Treadwell companies, the latter has been upheld by the Supreme Court at Washington, D. C.——The new 2500-hp. turbine at Treadwell was 'cut in' on January 19. While testing the machine, T. Rattray, of the General Electric Co., and other attendants, were severely burned by an oil switch accidentally exploding.

The Alaska Treadwell mills crushed 61,341 tons of ore in December, yielding a total of $127,714. Operating expenses totaled $85,017, and construction $62,443, leaving a loss of $21,024. The stock of broken ore in stopes was decreased by 32,137 tons.——The Mexican mine produced 19,040 tons of ore yielding $42,814. Including construction expenditure, there was a loss of $5984.——The United mill recovered $94,188 from 39,261 tons. Construction cost $28,494, but the profit was $12,744.

ARIZONA

There was heavy rain and snow in the central and southern portions of the state at the end of January, resulting in floods almost as disastrous as those of a month ago. Streets at Phoenix and at Globe, Miami, Glendale, Tucson, Bisbee, Tempe, Buckeye, and Arlington were under several feet of water on the 30th. Ranchers in the lowlands were forced to flee for their lives. The Salt river overflowed, the flood attaining a volume greater than the highest point known. The Santa Cruz, Gila, and Rillito rivers also filled their valleys. Globe and Miami were isolated for several hours.

Cochise County

On February 1 the Copper Queen and Calumet & Arizona companies will start a profit-sharing system, or sliding scale of wages with their employees at Douglas. This will be based on the price of copper.

Gila County

The annual report of the Old Dominion Co. of Maine for 1914 shows that dividends received from the Old Dominion Copper Mining & Smelting Co. at Globe totaled $860,409. The increase in value of shares held was $582,573, making $1,415,008 available, of which $1,173,412 was paid in dividends. The surplus at the end of 1914 was $433,064.

Mohave County

At 300 ft. in the United Eastern mine, east of the Tom Reed, the vein has been opened 16 ft., assaying $30 per ton. Sinking is to be continued to 500 ft. depth.——Good ore is still being opened at 300 ft. in the Gold Ore, at Gold Road.——It is reported that the Golconda zinc mine, 16 miles north of Kingman, is to be sold to an influential syndicate operating in Arizona.

CALIFORNIA

Amador County

The Argonaut at Jackson has paid a quarterly dividend of 30c. per share, or $60,000. N. S. Kelsey is superintendent.——A rich stringer has been cut in the Amador Queen, south of Jackson.——A 5c. dividend has been paid by the South Eureka company. There are about 300 men employed at present.——At Amador City the Keystone company has installed a motor-driven hoist, and the 40-stamp mill will soon be in full operation. Development down to 1400 ft. is encouraging. C. R. Downs is manager.

Butte County

According to James H. Leggett of Oroville, eucalyptus trees planted in the old dredge tailing nine years ago are now being used for telephone poles, fence posts, and other work. It is not necessary to level the rock piles. The young trees are

planted in the fall. His results with grapes grown on this material are well known, while figs peaches and apricots have done well. The theory of the success of fruit grown on dredge tailing is that the warmth of the rocks accumulated by day is slowly given off during the night, also the roots can spread with ease.

A good deal of coarse gold nuggets from 4½ to 37½ oz., from the Santa Claus claim, has recently been recovered from Squirrel creek, which joins the Feather river near Spring Garden tunnel. The gold is found on bedrock. E. A. Ludwick and others from Nevada have purchased the Gabbert quartz claims and are installing a hoist and compressor, and will prospect for the source of this gold.

Calaveras County

At the Royal property at Hudson, the 300-ft. level has been explored for 300 ft. south, showing 6 to 20 ft. of quartz, and 10,000 tons is broken ready to hoist. The manager, F. W. Page, states that tracks with loaded cars, as left years ago, are in good condition, walls standing well, and ore-bins are filled with ore ready to draw, also in good order.

Eldorado County

According to the *El Dorado Republican*, 'Promotion Edition,' gold mining in this county is less active than for 25 years. With few exceptions, only prospecting and development is being done in the quartz areas. However, this is not considered discouraging when the conditions are understood. Not much is being done between Placerville and Nashville. The Guildford Gold Mining Co. is working its mine by adits, and has 15 stamps crushing ore, in charge of A. Baring-Gould, two miles north of the former town. Sluicing has given place to drift mining at the Georgia Slide deposits near Georgetown. Limestone deposits are actively worked.

The old Springfield mine, which produced a large amount of gold down to 1600 ft., is to be unwatered and reopened by J. A. Finch, well known in Spokane. He is assisted by Enol McBoyle, who has been examining the property for some time.

Nevada County

(Special Correspondence.)—The Union Hill mine at Grass Valley has completed sinking the three-compartment shaft to the 800-ft. level. A station has been cut and driving is now in progress, the objective point being an ore-shoot that was developed through a winze sunk to a depth of 50 ft. below the 600-ft. level a year ago. This supplied ore for the operation of the mill from a stope 100 ft. long. This shoot is 125 ft. southeast of the shaft on the 600-ft. level, and has a slight dip to the southeast.

Grass Valley, February 1.

A new three-stage 500-gal. per min. Byron Jackson centrifugal pump is now working in the Golden Center mine. Development is quite satisfactory.

The North Star company has purchased the Muller and Walling claims, between the Nevada City and Spanish mines. This gives the company holdings of nearly two miles in length.

Shasta County

The agreement made with the Mad Ox Mining Co. by the owners of the Mad Ox claims at Stella for $12,000 has been extended, payments to be deferred to July 15, 1915, and May 15, 1916. The Company will pay 15% royalty on ore milled, the royalty to be applied to the purchase price.——Near Gas Point 1160 acres of placer ground has been located by San Francisco men, who already have about 1200 acres between this place and Igo.

Sierra County

The old Dead River mine is being reopened by Eastern people, in charge of R. E. Holmes.——An air-compressor and machine-drills are being installed at the Gold Bluff mine near Downieville. Salt Lake City people are interested.——A ventilating fan is now running at the Ruby mine.——At the Monarch Consolidated, known as the Lee, 20 stamps are working. D. McGonigal is in charge.

Trinity County

There is plenty of water in this county for hydraulicking, and the Trinity Consolidated, Testy, Lagrange, and others are busily sluicing.

Yuba County

Title to the Jefferson mine at Browns Valley is in dispute, and F. W. Johnson's claim to it is contested by B. Durris and others, a temporary injunction has been obtained against the latter from doing assessment work, both having been complying with the law.

COLORADO

Gilpin County

The Carr Mines Co. has completed its new mill. It consists of a crusher, Challenge feeders, ten 750-lb. stamps working at 53 drops per minute, amalgamating plates, two Gilt Edge tables, and No. 6 Willfley concentrators. The plant is motor-driven and crushes 30 tons per day. This type of stamp was installed to prevent sliming, and aid amalgamation.——The Fifty Gold Mines Co. of Black Hawk intends to remodel its mill, and erect a sampling plant for custom ores.——Regular shipments of gold-silver-copper ore are being made from the Pittsburgh mine in lower Russell gulch.

Lake County (Leadville)

Another serious fire, the fourth in the district in a few months, occurred on January 24, when the Big Five Operating Co.'s Big Four mine plant was destroyed, with a loss of about $20,000. The local opinion is that there is an incendiary in the district. The Colorado Power Co. has a contract to supply an electric hoist and compressor for the property.——Motors are being installed at the Penrose shaft of the Down Town Pumping Association.——The Canterbury hill and Prospect mountain tunnel scheme is gaining interest, and enough money will be raised locally.

High-graders put in several holes in the 700-ft. level of the Connor's lease of the Little Jonny mine, blasted out gold ore, and stole to the amount of $5000 one night last week.

Summit County

The annual meeting of the Rico-Wellington Mining Co. was held at Provo, Utah, on January 28. Jesse Knight is president, and J. C. Jensen, manager. The latter reports the mine in good shape for increased shipments of copper ore.

Net earnings of the Tonopah Placers Co. for the quarter ended November 30, 1914, totaled $101,982.

Teller County (Cripple Creek)

Another and lower drainage tunnel for this district is suggested by C. C. Hamlin, of Colorado Springs, the manager for the Granite company.——Official returns of ore from the Creson shoot show that 88 tons averaged 206 oz. gold per ton, and 76 tons, 105 oz., the total being worth $520,000.——Lessees are working down to No. 10 level in the Blue Bird.——Buildings and machinery are being erected by the Hondo company on Battle mountain.——Three cars of $15 ore have been marketed from the Cripple Creek company's Kohnyno vein in the Fortuna shaft at Victor.

IDAHO

Blaine County

A recent shipment of 42 tons of ore from 500 ft. in the Wilbert mine, 25 miles north of Arco, in the Dane district, averaged 56.85% lead and 21.4 oz. silver. This ore is sent direct to the smelter without concentration.

Clearwater County

The Pierce district placer claims are to be the scene of considerable work. The 100 acres of ground formerly owned by the American Placer Mining Co., on Orofino creek, are to be dredged by John M. Porter. Estimates give 25c. per yard.

The Hare company is operating a boat of 2000-yd. capacity per day. Another one is to be constructed for W. J. Harris about four miles from Pierce. A sawmill has been erected to cut 100,000 ft. of lumber for this dredge.

SHOSHONE COUNTY (COEUR D'ALENE)

A 100-ton mill is to be built for the H. E. M. Mining Co., operating three miles northwest of Wallace. During 1914 development consisted of 2479 ft., and expenses totaled $22,127. The sum of $20,000 will be raised for the plant. An adit is in 2276 ft., and a vein has been opened for 250 ft. Ben L. Collins, of Spokane, is secretary.——The annual meeting of the Mexico-Coeur d'Alene Mines Co., operating 12 miles from Thompson Falls, Montana, and eight miles from the Hercules mine at Burke, Idaho, was held in Spokane recently. The superintendent, John Burnham, stated that 17 ft. of milling ore has been opened in the lower adit. Shareholders decided to install a compressor plant and other equipment to be operated with electric power.——Some rich ore is being opened in the winze below the lowest level of the Caledonia at Wardner.

Dividend No. 209, amounting to $81,750, was paid by the Bunker Hill & Sullivan company on February 4. The total to date is $15,873,750.——The Tamarack & Custer Mining Co. held its annual meeting at Wallace on January 29. The present surplus is $100,000. Concentrate shipments amount to 1500 tons per month. Jerome J. Day is general manager.——It is probable that the Interstate-Callahan company will enlarge its present mill, instead of erecting a new one.——When the new electric pump is installed in the Hypotheek, sinking will be resumed to 1100 ft.——The Tuscumbia mine has been leased for 2½ years to G. Ehrenberg and A. Nelson. Ore will probably be treated at the Idora mill.——The Montana Power Co. will be ready to supply current on Beaver creek by April 1.

MICHIGAN

BARAGA COUNTY

(Special Correspondence.)—The discovery of vanadium ore was reported 27 miles east and north of L'Anse in November 1914, and the ground has been examined for the Michigan Geological Survey by W. E. Hopper. Owing to snow, only local geological conditions could be studied, but several of the statements of George W. McGhee in the *Mining and Engineering World* of December 12, 1914, concerning this property are incorrect, no carnotite being present, and the presence of vanadium ore being doubtful.

Houghton, January 24.

HOUGHTON COUNTY (THE COPPER COUNTRY)

In recent issues of *The Daily Mining Gazette* of Houghton are two interesting articles, namely, 'Recollections of Silver Islet,' by Samuel Brady, and 'Copper Mining in the Early Days,' subject for extracts from books printed for the Centennial of 1876.

The former describes the work done on the island since the discovery of silver there in 1868, by Gerald Brown, a Canadian government surveyor. The island, or rock, was only 40 by 60 ft. and only 3 ft. above the surface of Lake Superior. In rough weather it was swept by the waters, which destroyed the work in progress. The vein yielded considerable silver, ore averaging from $20,000 to $26,000 per ton in 1871-2, the metal then being $1.28 per ounce. During the second, third, and fourth years of the Company's work, dividends totaled $360,000. In March 1884 the shaft was down to 1160 ft., and a winze 70 ft. deeper, but shortage of fuel allowed the water to gain on the operators, resulting in a permanent shut-down.

In the second article, the history of the Copper Country is given. The Jesuit missionaries reported the existence of native copper in 1659 to 1666. An Englishman, Alexander Henry, made the first attempt at mining in 1771, near the forks of the Ontonagon river, where was a large mass of metal. In 1841, Douglas Houghton, state geologist of Michigan, made the first examination of the district. He was drowned on October 13, 1845, near Eagle river. Numbers of mines were started in 1850, using crude methods of extraction. The Cliff mine produced 22,374,588 lb. from 1853 to 1860. The Minesota was the important property of the Ontonagon area for 15 years, and was remarkable for its mass copper. In 1859 it employed 718 men, and yielded 1626 tons of metal worth $515,786. Freight to Boston was then $11 per ton, against $20 the previous year. Copper exports in 1860 totaled 8543.4 tons, an increase of 2000 tons over 1859. The following is a list of the mines in the district in the year 1860: Central Clark, Connecticut, Copper Falls, Eagle River, North American, Northwest, Phoenix, Pittsburgh & Boston (Cliff), C. C. Douglass, Isle Royale, Franklin, Hancock, Huron, Mesnard, Pewabic, Portage, Quincy, Adventure, Astec, Bohemian, Hamilton, Mass, Minesota, National, Nebraska, Norwich, Ogima, Ridge, Rockland Superior, and the Toltec. The Minesota is the most important of any of the mines mentioned in the district.

At the Isle Royale new mill, three sections of the steel frame are up, and equipment is being received for installation. No. 1 shaft of the mine is to be reopened, and will produce 'rock' at No. 11 level. Large shipments are being made to the Allouez-Centennial mill, in spite of stormy weather.

MISSOURI

JASPER COUNTY

The Weaver mill, near Carl Junction, was destroyed by fire during the third week of January. The mine has been closed for some time.——One man was killed and another injured by a fall of ground in the Llewellyn area, northeast of Joplin, on January 26.

MONTANA

With the first biennial report of the Department of Labor and Industry of this state for the year 1913-14, W. J. Swindlehurst, commissioner, appears the report of the inspector of quartz mines, W. B. Orem. He states that the mining industry is one of the most important of the country, supplying 65% of the freight traffic of the railroads. His report covers accidents, sanitation, ventilation, shafts and cages, electric power, explosives, a synopsis of the state's mining laws, mineral output, and the important mines of the counties. Silverbow county is covered by the deputy mine inspector, D. J. McGrath. There are also reports by the coal mine inspector, John Sanderson, and the boiler inspector, Percy L. Brown.

NEVADA

ESMERALDA COUNTY

Final returns of the Goldfield Consolidated for December are as follows: ore treated, 29,851 tons; net realization, $195,-119; costs, $5.67 per ton; and development, 2528 ft. at $5.66 per foot. In the Combination mine the 292-Z sill at 230 ft. produced 111 tons of $127.60 ore. Lessees mined 1166 tons worth $19,394, of which the Company received $10,584, less cost of transport and treatment.

In the Florence the incline rise is up 40 ft., but bad air has hindered progress. There is 9 ft. of $50 ore showing in the top.——A winze below 700 ft. in the Kewanas has cut the latite-shale contact at 840 ft. Four feet of low-grade quartz was cut between the two formations.

LANDER COUNTY

Stream tin was recently discovered at Battle Mountain, according to *Press Bulletin* 7 of the Mackay School of Mines.

NYE COUNTY

Six mines at Tonopah produced 10,997 tons of ore worth $223,906, during the week ended January 30.——The report of the Tonopah Mining Co. for the quarter ended November 30, 1914, shows that the value of ore treated was $588,138. Net earnings totaled $226,152, and sundry income $82,686, of which total $18,917 was spent in exploration and Moore Filter suit.

Dividend on October 21 was $250,000, and cash at the end of the quarter $88,691. Net assets are $1,698,769.

A fire-protection scheme is being installed at the Extension. Forty more leaves are being added to the filter to cope with the daily output of 270 tons.——Development in the Belmont continues excellent.——Ore is being sent from the Montana mine to the West End mill.

STOREY COUNTY

It has been decided to continue work on the lower levels of the Belcher mine on Gold Hill. The joint incline is being reopened in the fire area, and a temporary pumping plant is to be installed. The two pumps under water at 1500 and 1600 ft. will be recovered. Plans are now under way to consolidate the Belcher, Crown Point, and Yellow Jacket, adjoining companies, and this would result in economies and better mining results.

OREGON

BAKER COUNTY

(Special Correspondence.)—The Ben Harrison mine, near Greenhorn, which has ore blocked out estimated to be worth $900,000, and has heretofore been shipping the concentrate product of its 20-stamp mill to Tacoma, has decided, after careful tests, to install a cyanide plant to cost $65,000. Snow in the Greenhorn is now 42 in. deep, but a road is to be broken at once to the mine, and the new plant started as soon as possible. It is estimated that the saving effected will pay for the new plant in less than a year.

Greenhorn, January 26.

JOSEPHINE COUNTY

Mining men of Grants Pass discussed the appropriation for the state Bureau of Mines and Geology with the director, H. M. Parks, last week. The institution was declared of great value to the industry, and a biennial allowance of $50,000 is to be asked.

TENNESSEE

POLK COUNTY

The Tennessee Copper Co. is planning an extension to its acid plant. The Company's contract with the International

ACID PLANT OF TENNESSEE COPPER COMPANY.

Agricultural Corporation is still in force to supply acid. The improved copper market makes it possible to resume construction of other plants stopped early in August. A steel headframe has been erected at the McPherson shaft, a new furnace at the smelter, while machinery is to go to Copper Hill. The new hoist at Burra Burra and McPherson mines will double their capacity. About October 1, 1915, copper will be produced at the rate of 20,000,000 lb. per year, at a cost of perhaps 2c. per pound lower than at present. Ore reserves are estimated at 25 years' supply.

UTAH

JUAB COUNTY

Forty men, 32 lessees and eight on Company account, are working the Lower Mammoth, from 400 to 1800-ft. level. The Company is developing at 700 and 1000 ft. Some good zinc ore is coming from 1500 and 1800 ft.——The Eagle & Blue Bell is shipping a good deal of ore from 1700 ft.——The Dragon Consolidated is producing 200 tons per week. A new shoot of gold ore occurs at 600 ft.——Preparations are under way to resume work at the Mammoth.——There is a shortage of water for this part of the district.——Some fair gold ore is coming from 800 ft. in the Chief Consolidated.

SALT LAKE COUNTY

As part of the Magna mill of the Utah Copper Co. is under repair, several units of the Arthur plant were started last week. This will result in no increase of copper production.

Ore shipped by the Utah-Apex company in December amounted to 4157 tons of smelting material, 9172 tons for the mill, and 3093 tons of concentrate.——It is reported that ore has been cut in the Columbus Extension adit in the Alta-Big Cottonwood district.

WASHINGTON

FERRY COUNTY

(Special Correspondence.)—A further dispute has arisen at Republic. In this case the Lone Pine, Pearl, and Surprise mines, the Republic Mines Corporation (bankrupt), Republic Consolidated Mines Corporation, Western Union Mines Co., J. L. Harper, and A. J. Laughon are concerned. In brief, the last mentioned states that the Western Union company has failed to comply with an agreement made with him for the Republic Consolidated about the mines mentioned, therefore the Consolidated resumed possession of its properties. The Western Union company failed to meet its December payroll on January 25, 1915, and over 100 miners walked out. Liens have been filed on the assets of this concern, including ore, bullion, precipitates, and solutions in the San Poil mill, which plant is under option to the Western Union. All of its options have been forfeited. Mr. Harper is suing the Lone Pine-Surprise company for damages for alleged misrepresentation. A representative of the West Virginia people controlling the Western Union has gone East suddenly, and S. M. Croft, president of the Company, says he will meet the payroll and reorganize if necessary.

The affairs of the San Poil Consolidated mine and mill are under investigation, the Company being heavily in debt.—— The Ben Hur Leasing Co. has deferred its December pay-day, owing to the absence of a leading member of the Company.

Republic, January 30.

KITTITAS COUNTY

(Special Correspondence.)—The new year started with considerable activity in the Swauk district, in both placer and quartz mining.

The Cougar mine has started operations again, and considerable development will be done this winter, and as soon as the weather permits the 10-stamp mill will start crushing. George Marshall, of Vancouver, B. C., has charge of the property. Mr. Nettle, also of Vancouver, is now examining the mine. In the past, straight amalgamation has been used in the mill, and results have not been altogether satisfactory, and it is probable that the process will be changed.——C. B. Killson, owner of the Nellie quartz mine, has opened a 4½-ft. vein of fair ore in the shaft.——J. T. Sugars and J. F. Powers have taken a lease and bond on the Beckman placer claim. A drainage adit has been started from Williams creek, and 200 ft. has been completed. They expect to strike bedrock in about 100 ft. more. ——The Trilby gulch placer, owned by K. Enekel, has been leased by four miners who will start piping as soon as there is water. This placer has been a good producer and has been only partly worked.——What is of great interest to this district at present is the possibility of two large dredges being operated here in the near future. George T. Coffey, an Alaska mining man who came here last fall, has done a great deal of prospecting on Swauk creek, and with gasoline hoists and pumps he has pretty thoroughly prospected for about five miles.

This spring he will start the prospecting of Williams creek. He has taken a bond on about 35 claims here. If prospecting results are satisfactory, it is understood that two dredges will be built, one on Williams creek and the other on Swauk creek. Mr. Coffey will prospect Lions creek also, if he can secure the right-of-way up the gulch.

Liberty, January 7.

(Special Correspondence.)—Placer miners on Swank, Williams, Nelson, Lions, and other creeks in the Swank district are busy, and getting satisfactory results.

Liberty, January 27.

CANADA

Ontario

To lessen the unemployed problem at Timmins, the Hollinger company and town council have put men at work cutting cord-wood at $1.25 per cord. There is 320 acres of land nearby to be cut. The annual meeting of the Hollinger was held in Montreal on February 2.——At the Vipond, the Davidson vein has been opened 75 ft. on the 300-ft. level, and is from 4 to 6 ft. wide. The mill is treating 100 tons per day.——Development at 400 ft. in the Dome Lake continues satisfactory. A second clean-up at the mill produced $5000.——No. 4 shaft of the McIntyre mine is down to 600 ft.——The Crown Reserve company's profit in 1914 was $239,477, against $528,287 in 1913, and surplus after dividends $477,711.

MEXICO

Hidalgo

In cross-cutting south on the No. 16 level at a point 870 ft. east of San Guillermo shaft of the Santa Gertrudis, a vein has been cut 700 ft. south of the north vein. In the cross-cut the vein is 10 ft. wide, assaying 19 oz. silver and $1 gold per ton. Driving on this vein is in progress, and for the first 48 ft. assays 57 oz. silver and $4 gold per ton, the vein being wider than the drift.

Sonora

It is reported in Douglas, Arizona, that the Constitutionalists have raided El Tigre and commandeered considerable supplies.

AERIAL TRAMWAY OF SAN LUIS MINING CO., DURANGO.

The 'port' of Agua Prieta has been closed to the importation of food and merchandise for the south. This was ordered by the Carranzistas. Mining companies, including the Moctezuma and Tigre, will soon face a shortage if this is kept up.

PERSONAL

Gerald Brown is in New York.

Charles Janin was in New York last week.

H. Foster Bain has returned from New York.

Morton Webber sailed on the S. S. *Baltic* on January 27 for London.

T. A. Rickard returned to London on the S. S. *Lusitania* on January 30.

A. A. Boyd has been made superintendent of the Mt. Morgan mine, Queensland.

Scott Turner is in this country from Spitzbergen and has gone to Minnesota.

E. H. Leslie is at Columbus, Ohio, where he went to attend the funeral of his father, who died suddenly last week.

Charles T. Kruse has been appointed superintendent of the Jones & Laughlin mines on the Marquette and Menominee ranges.

Harry Huntington Miller has been appointed manager for the Cia. A. Minera Lo Increible, at its mines in El Callao district, Venezuela.

James Douglas, accompanied by W. H. Brophy, recently made his customary trip of inspection to the United Verde Extension in Arizona.

James F. McCarthy, president and manager of the Hecla Mining Co., at Wallace, Idaho, has been elected president of the Idaho Mining Association.

Herman A. Wagner is making an examination of the Crown King district, Yavapai county, Arizona, with a view to erecting a custom treatment plant.

George P. Vanier, chief chemist for the Pennsylvania Steel Co., at Steelton, Pennsylvania, has been awarded a certificate of merit by the Franklin Institute of Philadelphia, for his potash bulb for use in the determination, in industrial laboratories, of the total carbon in iron or steel.

The U. S. Civil Service Commission announces an open competitive examination for consulting mining engineer, to fill this position in the Bureau of Mines, for service in the field, at a salary ranging from $3000 to $3600, or at the rate of $10 per day when actually employed. The duties of this position will be to make examinations in different parts of the United States, including Alaska, concerning gravel gold mining operations, including dredge mining, hydraulic mining, and drift mining; and to prepare reports for the Bureau on this industry. As prerequisites for consideration for this position, the applicant must have had professional experience as mining engineer in connection with gold mining operations, extending over a period of not less than 10 years, of which not less than five years must have been given to professional work in connection with gravel gold mining operations. This professional work must have included operations in connection with dredge mining, hydraulic mining, and drift mining. Graduation with a degree in mining engineering, from a college or university of recognized standing, will be accepted in lieu of two years of the required professional experience. Applications must be in by March 2.

The San Francisco branch of the A. I. M. E. will meet at the new Clift hotel on Tuesday, February 9. C. E. Wells, metallurgist for the Selby Smoke Commission, will speak on the fume question.

The Michigan College of Mines has asked the state for $154,708 for maintenance and extraordinary expenses to cover the next two years.

The Northwest Mining Convention meets at Spokane on February 22-27.

THE MARKET PLACE

Weekly Summary of Prices of Shares and Metals

Metal Prices

San Francisco, February 4

Antimony	.18	18⅝
Electrolytic copper	15½	15¾
Pig lead	4.05	5.00
Quicksilver (flask)		$55.00
Spelter	8½	8⅝
Tin	.38	39½
Zinc dust, 100-kg. zinc-lined cases	.11	12½

On account of the rise in spelter, zinc dust is also moving upward. Fair supplies are now coming from Australia.

EASTERN METAL MARKET

(By wire from New York.)

New York, January 4.—Copper is quiet but firm, lead quiet, and spelter strong and excited, as domestic supplies are low and foreign demands heavy.

Metal quotes in the delayed telegram of the week ended January 28 were as follows: copper, 13.75, 13.87, 14.00, 14.00, 14.12, and 14.25c.; lead, 3.70c. every day, and spelter, 6.55, 6.75, 6.75, 6.87, 7.12, and 7.25c. per pound.

The past month's markets are discussed on the next page of this issue.

COPPER

Prices of electrolytic in New York, in cents per pound.

Date.		Average week ending

May	58.21	....	Nov.	49.12	....
June	56.43	....	Dec.	49.27	....

The past week has shown a decided weakness in silver. Owing to shortage of power at Cobalt, Ontario, the yield there will be reduced perhaps 25% for some time. The Mogollon district, New Mexico, has had troubles, resulting in curtailment. Exports of metal from San Francisco to the Orient in January were worth $779,000, say 1,600,000 oz. The Tonopah Mining Co. had 546,386 oz. stored on November 30. The Nipissing shipped 241,145 oz. last week.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Week ending			
Jan. 7	51.50	Jan. 21	52.50
" 14	50.00	" 28	52.50
		Feb. 4	55.00

Monthly averages.

	1914.	1915.		1914.	1915.
Jan.	39.25	51.90	July	37.50	....
Feb.	39.00	....	Aug.	80.00	....
Mar.	39.00	....	Sept.	76.25	....

Apr.	4.98	....	Oct.	4.75	....
May	4.91	....	Nov.	5.01	....
June	4.84	....	Dec.	5.40	....

Spelter became stronger on January 29, the price going to 7.70c., New York, and 7.60c., St. Louis. London quotation was £37 10s. per ton. Bids for ore at Joplin ranged from $58.50 to $65, the highest being $68 per ton.

ANTIMONY

This metal, like copper and spelter, was greatly affected by war influences in January. First of all, England placed an embargo on exports from that country. Russia bought up all the Chinese and Japanese antimony she could, and the Japanese bought back some of the contracts for future delivery they had entered. Domestic buying was almost nil in most of the month, though near its end some domestic consumers woke up and skirmished to find metal they could buy. Prices ranged during the month from 13 to 15c., and 16.50 to 20c. per pound for Cookson's, Hallett's, and other brands on the market.

New York Metal Review

Copper prices have advanced under the stimulus of an improved export demand and that from American makers of ammunition whose products are destined for the warring nations. Exports, however, are still far below normal, and the general domestic demand is anything but satisfactory. Lead was reduced in January because of the slow domestic demand and large production in 1914, which were not offset by exports, though these were good. Because of the heavy demand for brass-mill spelter, either directly or indirectly for export, its prices have soared and broken records. Tin had a quiet month, but the trend of prices was upward. In antimony there has been a large advance, following the action of foreign governments in taking all they could get, while England has placed an embargo on exportations from that country. In the metal-working industries generally, including iron and steel, the advances in both prices and activity of recent weeks are being held, but the gains are slow. The railroads are disappointingly backward in developing prospective purchases, though they are doing better. In the shipbuilding field the outlook is brightest, as enough vessels have been placed to make most of the Atlantic Coast shipyards busy, and more orders are pending. Two ships have been ordered from the Maryland Steel Co. by the Hawaiian-American line. The exportation of metal-working machinery continues on a large scale, one agency alone having placed orders for about 400 machine tools for export last week. Here and there manufacturers are rushed night and day, but the operations of many others are at low ebb.

COPPER

In January the price of electrolytic reached the 14c. level for the first time in seven months. The war, which at first caused the demoralization of prices, eventually sent them upward. The quotation became 14.12½c. cash, New York, on January 21, having advanced from 13.87½c. Lake reached 14c. on January 19. Throughout the month the domestic demand was quiet, and it was evident at all times that the brass and copper mills were not being called on even to a fair degree for commonplace products. With those used in the art of war, it was different. In the first few days of the month, electrolytic was nominal at 13c. cash, New York, but Lake was in strong demand at 13.50c. to 13.75c. Of the latter, the ammunition makers were taking large quantities. In the second week of the month the strength of the market in Europe began to exert more influence here, and by January 12 electrolytic was up to 13.62½c. Re-sale copper, which had been in evidence up to this time, was withdrawn. Lake was quoted on January 12 at 13.75c., with some brands commanding a premium. From the middle of the month it became more and more apparent that European sales were increasing, and prices went up with the demand. It was reported, for instance, and generally accepted, that Russia had bought 25,000,000 lb., later increasing the amount to 40,000,000 lb., all for shipment *via* Japan, where at least some was to be manufactured into ammunition. Government figures showed that the exports for the week ended January 23 amounted to 23,057,055 lb., against 7,836,759 lb. in the previous week. In the week ended January 9, the exports totaled 16,884,783 lb. Of the amount exported in the week ended January 23 (23,057,055 lb.), France took 14,927,323 lb., Italy 4,114,324 lb., and England 3,489,437 lb. In the eight weeks ended January 23, the total of exports was 93,936,426 lb. While these figures are encouraging, in view of existing conditions, it will be seen that exports are considerably under normal. The elimination of Germany as a customer is severely felt. Europe usually takes between 70,000,000 and 80,000,000 lb. of copper per month. In March 1914, when the record was broken, 89,562,166 lb. was exported. On January 26 Lake was quoted at 14.62½c. and electrolytic at 14.37½c., cash, New York.

High ocean freights, due to the scarcity of vessels, hampered foreign business, and materials needed by the allied nations were moved when other kinds of cargo lay on the steamship piers for days. One New York firm, nevertheless, did a good business in exporting copper locomotive fire-box plates to various European countries, which formerly had obtained them from Germany. The quotation for hot-rolled sheet copper was advanced ¼c. on January 16, to 18¾c.; on January 21, to 19c.; and on January 25, to 19½c. The announcement that the monthly statements of the Copper Producers' Association would be abandoned was a disappointment to many, though they hardly were surprised, as the producers have never been unanimous as to the wisdom of issuing the statements.

LEAD

Domestic consumers did not figure prominent in the lead market at any time in January, and such strength as was shown came from the export demand, which was fairly good. In 11 months of 1914 (not including December), 49,482 tons was sent out of the country. The New York quotation was 3.80c. until January 11, when the American Smelting & Refining Co. caused great surprise by reducing its price to 3.70c., a reduction of $2 per ton. The decline was attributed to the light domestic demand and to the figures of the U. S. Geological Survey, which showed that production had increased about 100,000 tons in 1914. The large production made the trade wonder that prices had kept up as well as they had. Toward the close of the month the buying for export was particularly good.

SPELTER

A continued export demand for spelter and heavy buying by brass mills engaged in the manufacture of war materials caused spelter to soar in January. The New York price was about 5.75c., January 5; 6.05c., January 12; 6.25c., January 19; and 7.50c. January 26 and 28. Brass-mill spelter brought more than its usual advance over prime Western; in fact, it was principally the brass-mill grades which were in large demand, and the higher prices of ordinary grades were largely sympathetic. Toward the end of the month the market was much upset; choice brands were scarce and commanding high premiums. Sales were made up to 13.50c. Both Russia and England took large quantities. Records were broken when the price exceeded 7c., and some makers of galvanized sheets withdrew their quotations on that product. The price of sheet zinc in carload lots at the mill was also withdrawn.

TIN

Trading in tin was quiet almost steadily throughout the month. In December, arrivals at Atlantic ports amounted to only 860 tons, deducting 240 tons exported to Russia. Of the December deliveries, 1900 tons, 400 tons arrived at Pacific ports. Despite the small arrivals, the market was but little affected, although the situation under other circumstances would have sent prices skyward. The total deliveries in 1914 were 41,700 tons, against 43,900 in 1913, a falling off of 2200 tons. January 1 there was in stock and on dock and landing, 1386 tons. The total world visible supply, December 31, 1914, was 13,396 tons, against 11,483 tons November 30, 1914, and 13,893 tons December 31, 1913. Price levels of the month may be broadly indicated as follows: January 5, 33.25c.; January 12, 33.35c.; January 19, 33.85c.; January 20, 34.12½c.; January 25, 35.65c.; January 28, 36c. On January 14 a representative of a London house endeavored to start business by offering 33c., but the concession offered made consumers timid and they stayed out of the market. Throughout the month buying was principally of small amounts for immediate shipment to satisfy urgent needs. In the last week of the month there was an unexplained rise in prices at London, the advance being £13 10s. between January 19 and 27. The belief was that a scarcity of the metal existed in London because of the difficulty in unloading vessels at that port.

Current Prices for Oils and Candles

(Corrected monthly by Standard Oil Co., California.)

All prices are f.o.b. San Francisco except where otherwise specified, and are subject to change without notice.

Granite Mining Candles	Per set, cents	Granite Mining Candles	Per set, cents
6s-12 oz.-40s	8¾	6s-14 oz.-20s	9½

Zinc sheet, No. 9—18 by 84, drum, per 100 lb.	No quotes	

*Extra charge for packing nitric acid for shipment to conform to regulations.

Roessler & Hasslacher quoted as follows on January 15:

Ammonia, anhydrous, in 50-lb. cylinders, per lb.	$0.27
Arsenic, white powdered, in 500-lb. bbl., per lb.	0.05
Cobalt oxide, black, in 10-lb. tins, per lb.	1.05
Cyanide, potassium, 38.4% cyanogen, per lb.	0.27
Cyanide, sodium, 51% cyanogen, per lb.	0.25
Sodium, metallic, in 1-lb. tins, per lb.	0.40
Zinc dust, in bbl. 1600 lb.	0.12

The chemical trade shows further settling to normal.

COMPANY REPORTS

GIANT MINES OF RHODESIA, LTD.

This Rhodesian company made a profit of £34,189 in the year ended June 30 1914. There was 123,320 tons of ore treated yielding £99,577. Costs totaled $2.45 per ton.

CONSOLIDATED GOLD FIELDS OF NEW ZEALAND, LTD.

The third quarterly report of this Company shows the following results:

	Wealth of Nations.	Blackwater	Progress.
Development, feet	686	719	1,230
Ore treated, tons	6,800	13,647	7,220
Yield per ton	$7.64	$8.79	$5.98
Cost per ton	$4.48	$5.28	$4.90
Operating profit	$22,500	$49,000	$8,600

The total working profit was $80,100, but shaft-sinking, development, prospecting, and experiments cost $57,600, leaving a net profit of $22,500. A dividend of 5% (24c. per share) was paid on the Blackwater company's shares.

ARAMAYO FRANCKE MINES, LTD.

This Company operates in the North and South Chichas provinces of Bolivia, and the report covers the last financial year. There was 43,366 tons of tin ore treated, yielding 3442 tons of *barilla*, or concentrate. The output in the previous year was 3694 tons. There was 58 tons of wolfram sold, compared with 281 tons; copper matte, 342 tons, a new source of revenue; and bismuth and rich silver-tin ore. Sales of all products, including 4218 tons of tin, realized £352,049. The net profit in Bolivia was £145,765, against £153,177 in the year ended May 31, 1913. Tin mining was suspended in August on account of the war, but as sea risks are considerably less, work has been resumed. From June to November 1914 the output was 1962 tons *barilla*, 384 tons silver-tin ore, 25 tons wolfram, 33.7 tons copper, and 18 tons increase of bismuth. Four dividends of 12c. per share or £59,684 were paid, and £30,000 debentures redeemed. Another dividend has since been paid and another declared, also payment of £30,000 debentures. The balance carried forward is £90,364.

MT. MORGAN GOLD MINING COMPANY, LTD.

The report of this well known Australian company covers the half-year ended November 29, 1914. During this period the total revenue was £502,382 of which £438,546 was spent in operating, development, and depreciation. The surplus was therefore £63,836, from which £50,000 was distributed as a dividend. Including the previous balance, that carried forward to the current year is £134,189. The various funds have a total value of £341,040, and net liquid assets £400,721.

The general manager, B. Magnus, reported as follows: It is hoped that new work to be done at the mine to equip it for the maximum output will be finished during the present term. Development totaled 2484 ft., and ore reserves consist of 1,127,000 tons of high and 1,849,000 tons of low-grade material. Ore mined down to 950 ft. consisted of 171,355 tons, against 131,135 tons in the previous half-year. The Many Peaks pyritic mine supplied 32,112 tons. The new blast-furnaces started in July and have reduced costs of treatment. Concentrate from the flotation plant gave some trouble, on account of its fineness. The smelter treated 179,939 tons of mixed ores, yielding 4594 tons of copper and 58,509 oz. gold. The concentrator treated 31,274 tons of 2.36% copper and $5.36 gold ore and has shown that it can handle 500 tons per day. This mill was described in the *Press* of December 26, 1914.

LENA GOLDFIELDS, LTD.

This Company controls one of the greatest placer properties in the world, and the report covers the year ended September 30 1914. The operating company in Siberia is the Lenskoie, of which the Lena Goldfields holds 60.62% of the shares. The Lenskoie company's profit was £207,973, from which £87,302 was paid in dividends at the rate of 7.50 rubles per share, the Lena company receiving £52,533. The latter had a cash balance of £340,408 at the end of its financial year.

The mine report is by the consulting engineer, C. W. Purington, well known in the United States. R. E. Smith is general manager. He states that in the four divisions of the property a total of 873,633 cu. yd. of gravel was washed, yielding 370,210 oz. gold valued at £1,381,993. Including purchased metal and gold in slag, the total was 399,111 oz. worth £1,489,881. The areas controlled by the Lenskoie have a recorded output of over £40,000,000 ($195,000,000). A higher recovery was made by adopting American methods, and an engineer from the United States is superintending other changes. The cost of operation and Petrograd expenses was $7.13 per yard, a reduction from the previous year. Three classes of reserves are 2,134,890 cu. yd., valued at £3,595,000; 1,949,500 cu. yd., valued at £2,781,000, and 56,000,000 cu. yd., worth £5,113,000, respectively. The latter can be worked by hydraulicking. The estimated profit in these reserves is £3,633,700. At the end of the year there were 7636 men employed.

An interesting comparison between working the Bodaibinsky area by drifting and sluicing is given, showing the following results: by drifting, 1,270,000 cu. yd. averaging $5.23 per yard, giving a loss of £307,000, converted by adoption of the hydraulic method treating 12,700,000 cu. yd. averaging 4.4c. per yard into a profit of £852,000. The reserves mentioned by no means exhaust the possibilities in this area for sluicing, and extensive areas of bench gravels bordering the Bodaibo valley can be worked in this way also, without elevation of tailing.

OROVILLE DREDGING COMPANY, LTD.
OROVILLE DREDGING, LTD.

It may be explained that the Oroville Dredging Co., Ltd., is the English concern which controls the American operating company, Oroville Dredging, Ltd., also the Pato and Nechi companies operating in Colombia, Central America.

The English company's report covers the term July 1, 1913, to September 30, 1914. The directors state that the American company resumed payment of dividends in February 1914, and distributed two of 12½c. per share. The English company received £31,929, and with previous balance was able to pay two 6d. dividends, absorbing £31,483. The American company's loan account has been reduced from £30,949 to £24,260. To December 8, the Pato dredge had recovered $67,538 from 474,428 cu. yd. from one area, and $848,114 from 1,400,340 cu. yd. in the tested area. W. A. Prichard's report was published in the *Press* of February 6. The Nechi Mines (Colombia), Ltd., was formed in February 1914 with a capital of £140,000, and a dredge is now under construction.

The general manager of the American company, W. P. Hammon, resigned during the term, and the report for the year ended July 31, 1914, is signed by Charles W. Gardner. In August 1913 all the separate dredging companies controlled were consolidated into the present Oroville Dredging, Ltd., excepting the Boston Machine Shop Co. Gold returns represent the work of three dredges, No. 4 and Exploration 2 and 3. At present, February 1915, only two boats are at work. The three mentioned excavated 2,897,557 cu. yd. of gravel yielding $251,599. Of this, $134,353 was profit. The sum of $64,146 was spent in administration in London and San Francisco, dismantling dredges, etc. The surplus at the end of the financial year was $389,307. Dredge operations will be dealt with in another issue of this journal. The Boston Machine Shop made a loss of $2611.

MINING DECISIONS

PAROL AGREEMENT TO MINE—REVOCABLE.

A verbal agreement between plaintiff and defendant that plaintiff should have the right to mine a certain area of coal in defendant's mine, cannot be enforced by plaintiff where defendant rescinded the same before any operations were commenced.

Christian v. Smith Coal Co. (Alabama), 66 Southern, 641. November 7, 1914.

MINING LEASE—ACQUIRED BY VERBAL PERMISSION

Where plaintiff has given defendants verbal permission to enter upon and mine her land for ore, and, relying on such permission and subsequent assurances, defendants had expended considerable labor and large sums of money in developing work, and had tendered to plaintiff 10% royalty on the first sale of ore, the transaction was construed as vesting in defendants a statutory mining right for a period of three years, under the laws of Missouri.

G. M. Mining Co. *v.* Hodge (Missouri), 170 Southwestern, 689. November 27, 1914.

OIL LEASE—FAILURE TO OPERATE

Where plaintiff's vendor executed to defendant an oil and gas lease in consideration of $1 and defendant's agreement to pay a royalty, with a stipulation that the lessee should begin prospecting on and developing the lands described in the lease or other lands within four miles of those so described, within a year from date, a failure to prospect or do any development work for more than 10 years constituted an abandonment of the lease, though defendant did begin operations on other lands within four miles of those leased within the time specified.

Mansfield Gas Co. *v.* Parkhill (Arkansas), 169 Southwestern, 957. October 5, 1914.

MINING LEASE—SURFACE RIGHTS

A mining lease granted the lessee the right to construct on the premises all facilities necessary to market the ore taken from the land, including railroads. Held that this did not confer upon him the right to construct or authorize the construction of a railroad for general traffic on the land in question, or for any purpose except in aid of the mining operations and the transportation of ore to market. The lessor retains the right to possession and ownership of the surface, except as to such portions as are needed to carry on the mining operations.

Howell *v.* Cuyuna Northern Railway Co. (Minnesota), 149 Northwestern, 942. December 11, 1914.

MINE OWNER NOT LIABLE FOR CONTRACTOR'S NEGLIGENCE

A mine owner employed an independent contractor to work the mine, agreeing to furnish certain enumerated appliances and apparatus, but the contractor to furnish the labor, assume all risks for accidents, and operate the mine in accordance with the best methods and mining laws and to the satisfaction of the owner and its engineer. Owing to the absence of a derailing switch at the mouth of the mine, an accident occurred resulting in death to one of the contractor's employees, whose administrator then sought to hold the mine owner liable. The derailing switch was not among the appliances required under the contract to be furnished by the owner. Held that the administrator of the estate of the employee who was killed could not recover against the mine owner.

Connors-Weyman Steel Co. *v.* Kilgore (Alabama), 66 Southern, 309. November 7, 1914.

New Machines and Devices

Sectionalized Water-Wheel

In view of the many comments at the present time with reference to packing for export, it is interesting to observe how one American firm meets exceptional conditions. The accompanying illustration shows a shipment of a tangential water-wheel, made by the San Francisco shops of the Pelton Water Wheel Co., to the Estaca Mining Co. of Mexico. The wheel is a 100-hp. unit for direct connection to an air-compressor. It was necessary to sectionalize the entire shipment for mule-back transportation.

THE RUNNER ASSEMBLED.

The small halftone shows the Pelton-Doble runner assembled; the top one of the other halftone shows it taken down for packing; the bottom one shows the reverse curve needle nozzle assembled; the method of sectionalizing being plainly shown; and the middle one shows the entire equipment boxed and ready

ILLUSTRATING HOW TO PACK A SECTIONALIZED WATER-WHEEL.

for shipment. Each package is properly numbered; the gross and net weight in pounds and kilograms, the cubic capacity plainly marked, and the purchaser's private mark properly displayed. These illustrations are well worth the study of any firm interested in foreign trade, while purchasers of equipment can take this shipment as a model on which to base specifications. All parts are carefully marked to place before knocking down in order to facilitate reassembly after arrival at the mine.

Commercial Paragraphs

The Hardinge Conical Mill Co. has received an order to supply three of its largest size ball-mills for the Moose Mountain, Ltd., Sellwood, Ontario, Canada. Also sixty 10-ft. diameter mills for the Anaconda Copper Co., twenty of which are to be installed at once, the others to follow during the year.

Driggs-Seabury Ordnance Corporation, Sharon, Pennsylvania, has published a very attractive catalogue devoted to the Vulcan service truck. This truck is a heavy duty vehicle designed to meet the requirements of rugged usage, and is made in several sizes up to 7-ton capacity.

Sangamo Electric Co., Springfield, Illinois, has recently issued Bulletin No. 40, which is devoted to the alternating current watt-hour meters manufactured by this Company. The bulletin is fully illustrated and contains a large amount of data regarding the construction and operation of this type of meter.

Lehigh Car Wheel & Axle Works, Catasauqua, Pa., in catalogue 50 describes the 'Fuller Quality Products' as manufactured by this Company. This Company is one of the pioneers in the manufacture of chilled charcoal iron castings of every description, especially designed for service requiring great strength and durability.

Busch-Sulzer Bros.-Diesel Engine Co., St. Louis, Missouri, has recently published a bulletin containing the results of tests which were performed to determine the economy and efficiency of the Diesel engine under fluctuating and steady loads. These tests show a fuel consumption of a little over six gallons for 100 net brake horse-power hours.

The Asbestos Protected Metal Co., Pittsburgh, Pennsylvania, announces that on February 1, the general offices of the Company, including the executive, accounting, sales, and engineering staffs, will be moved from the Beaver Falls plant to the First National Bank building, Pittsburgh. The manufacturing operations of the Company will continue as heretofore at Beaver Falls, Pennsylvania, and at Waltham, Massachusetts.

The International High Speed Steel Co., of New York, has acquired a tract of nine acres of land at Franklin, near Rockaway, New Jersey, on which it will erect a large steel plant for the manufacture of 'Bulldog' brand of hollow and solid mining drill steel in all sections, shapes, and sizes; and also of high speed, tool, and automobile steels of every description. It is expected that the plant will be in operation by April and will, when completed, give employment to several hundred men.

Western Electric Co., New York, has recently devoted considerable attention to the perfection of the mine rescue telephone equipment. This equipment, which provides a reliable and flexible means of constant communication between a rescue crew in the mine and the directing force at the surface, has been developed in collaboration with the Federal Bureau of Mines. The final design is such that it will meet successfully all the conditions that may arise in mine rescue work. With the new equipment, it is possible for a rescue crew of from one to five men to be connected to the circuit at the same time. The throat transmitter does not interfere with the use of standard oxygen helmet, and a high grade of transmission is obtained even with all five sets in use and all the coils of wire cut in, making a total transmission line of 3300 feet.

SHAFT-SINKING AT KELVIN, ARIZONA.

By A. L. Flagg 250

Interesting details covering methods and costs of sinking a three-compartment, 6 ft. 4-in. by 16-ft. shaft, which was sunk 220 ft. from a station itself 245 ft. from the surface, are given. The shaft was sunk using Sullivan piston drills, mounted on cross-bars and drilling cut holes 10 to 11 ft. deep, with back holes 7 to 8½ ft. Blasting was with Hercules gelatin powder, and 'delay action' fuses of the California Cap Co. There were only 6 misfires in a total of 795 holes fired. The total number of shifts was 218, of which 204 were consumed in actual sinking. The cost was $48.13 per foot.

ORE TREATMENT BY THE VANDERCOOK PROCESS.

By E. C. Morse 254

The Vandercook process is one of combined amalgamation and cyanidation. In applying it, numerous ingenious modifications of the usual types of classifiers, agitators, thickeners, and filters have been made, and a filter is employed in which no cake is built up. Mr. Morse describes the apparatus and gives results of a test on ore from the Hope mine in Washington.

NEW FILTERING PROCESS AT THE TREADWELL CYANIDE PLANT.

By W. P. Lass 256

Starting from the basis of a Kelly press, Mr. Lass tells how an improved type of filter has been built up which is now in use at Treadwell. It consists of a drum with internal leaves so arranged as to permit quick and easy filling, washing, and discharge by internal sluicing.

THE LADD MANGANESE MINE.

By Samuel H. Dolbear 258

A description of one of the older manganese mines near Livermore, California, which has recently been sold to the Western Manganese Co., which is to reopen it.

A SUBSTITUTE FOR DANISH PEBBLES 259

A note on the use of lava chips at the 'sand cement' plant of the U. S. Reclamation Service on the Boise project in Idaho. Under the particular conditions present, a marked saving was possible as a result of the substitution.

SPECIFIC-GRAVITY APPARATUS.

By J. M. Lillygren 260

Notes and sketches on a convenient form of apparatus for making specific gravity determinations with pulps. It is in use at the mill of the Aurora Con. Mines Co., Aurora, Nevada.

CALIFORNIA petroleum producers take little comfort in having broken all records for production in 1914, since production is still beyond consumption. A dividend record of over eleven million dollars, however, is not bad in a 'bad' year.

SHIPMENT of 4000 sacks of ore having an average value of $1000 per sack, from the Cresson mine at Cripple Creek, is reported in the local papers. Applying any probable 'factor of safety' to these figures, the Cresson find still remains one of the most remarkable in a district famous for high-grade ore.

PLANS for the meeting of the American Institute of Mining Engineers at New York, beginning on February 15, insure a good meeting. The annual dinner promises to be an unusually interesting event, while the announcement of the vote on the proposed changes in the constitution of the Institute is awaited with interest.

THE BUSINESS of the United States Steel Corporation in 1914 amounted to only $71,661,149, the smallest in the history of the concern. Even in 1908, after the financial crisis, the total was $91,847,710. The greatest year was in 1907, when the revenue was $160,964,674. In the course of one year net profits were cut virtually in half, and whereas in 1913, 11.17 per cent was earned for the $508,000,000 of common stock, in 1914 nothing was earned for the common and only 6½ per cent for the preferred stock. Consequently, after the payment of 3 per cent on the common stock, there was a deficit of $16,965,687. Never before was the Company unable to show its 7 per cent preferred stock dividend safely earned.

WASHINGTON advices are to the effect that the Administration bill for leasing the coal, oil, and phosphate lands, has been reported favorably to the Senate. It seems probable that the bill will become a law despite the opposition of able and influential senators who see nothing of good in a leasing system. We have already expressed our approval of the system and its application to these particular substances in which it is possible to make approximate measurements at least, of the quantities of mineral in the land leased. Indeed, we have no strong feeling of opposition to a general leasing system, but we recognize that the situation as to coal mining and gold mining, for example, differs greatly, and, whatever might be the theoretical benefits of any system, practically these would not be realized in the face of virtually unanimous opinion against it of those concerned. Since coal mining, petroleum production, and even phosphate mining, are now largely conducted upon leased land, extension of leasing to mines on public lands is not revolutionary. It has much to commend it, permits immediate development, and does not close the way to any later change that may prove desirable.

A COMPREHENSIVE study of gold-dredging has been undertaken by Mr. Charles Janin, acting for the United States Bureau of Mines. It is planned to cover all North American operations and to make a careful analysis of the possibilities and limitations of the process as a first step toward solution of the general problem of reviving placer mining. At the same time, Mr. J. M. Hill will make a comprehensive study of the placer deposits of the country for the United States Geological Survey, the work being closely correlated with the studies of methods undertaken by Mr. Janin. At least a year will be devoted to these investigations and the result is certain to be the most comprehensive and valuable reports upon placers and placer mining that have ever been made.

THE SHIP PURCHASE BILL

Opinion is divided as to the ship purchase bill which, like the jitneys on Market street, has been obstructing traffic at Washington. Well informed men in the shipping business recognize that any material increase in trade would find the United States short of transportation, without regard to the flag under which carriers sail. Many boats have been sunk, others interned, and still others withdrawn for naval or army use. The obvious thing to do is to buy the idle boats and set them to work, and it is conceivable that they might be so routed as not to provoke resentment on the part of the warring powers. That is, it would be conceivable if such matters were handled on a common sense business-like basis. Unfortunately they are not. Our navigation laws are radically defective and greatly increase the cost, to no good purpose, of operating American ships. If it were merely the difference in wage cost we might fairly expect to overcome the handicap, just as American mine managers have where facing a high wage scale. The labor cost is, however, only one item, and the men who

know how to re-write our navigation laws intelligently either do not have the power or have not the confidence of the country. Ship owners generally believe, and not necessarily selfishly, that the situation can be best met by a system of ship subsidies, but no one familiar with public opinion, especially in the Middle West, considers that this plan, whatever its merits, lies within the domain of practical politics. It may be good or it may be bad—it is unnecessary to decide the point—but any Congress that established a system of ship subsidies would leave few survivors at Washington after the first succeeding election. The situation calls for a remedy that may not be ideal, but which must be the best that is possible under the circumstances.

It has already been shown, in the case of Alaska, that the people will approve government ownership of transportation lines while they will not permit the giving of government aid to private lines, as was done in the past. We believe that the President is right and that public opinion will sustain government ownership of ships. Also we feel reasonably confident that unless something is done there will be a serious shortage of transportation which will react upon many American industries. It does not follow that the ship purchase bill cannot be amended to advantage, though our worst mistakes in legislation have been due to over-specification of details. The Panama canal was well built and without scandal, in large part because the men in responsible control had a free hand, and it would seem that the principle that power should go with responsibility might well be followed in embarking upon such difficult and complex a business as the ownership by the United States government, of merchant vessels.

From a naval point of view, no policy would strengthen the fleet so effectively as to have the new merchant marine actually owned by the government and operated by naval reserve officers. The type of ships needed most also fits into this plan, since in war time it is fast boats that are needed, and in establishing new trade lines it is fast communication that is most necessary. Trade goes from Chile to London and Hamburg to no small degree because of the interest saving on drafts and on shipments, resulting from fast mail service. It is everywhere recognized as proper that the government should furnish good mail facilities regardless of immediate returns, and if a combined rail and water express line could be established from the eastern cities through any convenient Gulf port and the Panama canal down the west coast of South America, it would be one of the most effective stimulants to trade. This is only one of the many possibilities. Wherever the fast boats were put into service they would make work for the slower profit earning freight boats that private initiative might well be expected to furnish, and whatever boats be put to work, they, by so much, increase the carrying capacity available for the world's commerce, and particularly that part in which the people of the United States are interested. The ship purchase bill may be far from perfect, before final passage it seems certain to be materially amended, but essentially it appeals to us as a sensible effort to meet a difficult situation, and we have failed to note any alternative proposal that was at the same time better and politically possible.

CANADA AND CANADIAN NICKEL

Canada is populated with loyal sons of the British Empire, and it also produces a considerable part of the world's supply of nickel, which is used in making armor plate for war vessels, and to a minor degree in the manufacture of munitions of war, such as nickel-jacketed bullets. In the early days of the war the idea occurred to Canadians that possibly some of the nickel employed by the enemies of Great Britain was derived from Canada, and by reiteration the fear grew until it became an obsession. Not long ago a Montreal daily paper published a cartoon showing a British battleship being torpedoed by a German submarine, with the accompanying legend, "Sunk by Canadian nickel." That neither torpedoes nor submarines contain appreciable amounts of nickel is a mere detail; the underlying idea is a patriotic one, which must be regarded with respect.

The two producers of nickel in Canada are the Mond Nickel Company, Ltd., and the International Nickel Company. The former is a British corporation which refines its nickel in Wales and, being under the direct control of the British military authorities is, of course, beyond suspicion. The International Nickel Company is an American corporation which refines its nickel in New Jersey, and the weight of suspicion at once fell upon it. It was at first rumored that the American company was controlled, or at least in part owned, by the Krupp interests, but the most cursory investigation was sufficient to prove conclusively that such an assertion had no basis of fact whatever. It was next charged that the International Nickel Company was selling its product to foreign buyers, some of whom would presumably attempt to take advantage of the high prices in Germany by forwarding nickel to that country. Since the International Nickel had taken precautions, soon after the war broke out, to clear itself of any such suspicion by placing all its foreign business in the hands of its English agents, it was equally easy to show that this was also not the case. That these facts are fully recognized in well informed circles in Canada is made clear by the editorial comment in the January 15 issue of our excellent contemporary, the *Canadian Mining Journal*. It is now proposed, however, to force the International Nickel Company, by appropriate legislation, to abandon its refining plant in New Jersey and carry on its refining in Canada, thus placing the industry wholly within Canadian control. The problem thus at once passes out of the domain of national patriotism into the more exact one of economics, and the factors which govern the situation are business relations into which it will be profitable to inquire more deeply before taking action.

During 1913 there was imported into the United States approximately 47,500,000 pounds of nickel in the form of matte. Of this about 3,000,000 was derived from New Caledonian ores smelted into matte near Antwerp, and forwarded to this country for refining in order to avoid the 10 per cent duty imposed on imports of metallic nickel. The remainder was derived from Canada, and of the total amount of refined nickel produced, a little less than one-half was consumed in the United States and the remainder exported. Very little of this nickel was returned to Canada, only about one-eighth of one per cent of the total. The fundamental question is therefore whether it is better economy to make Canada the production centre from which to export its entire product to the rest of the world (in the case of the United States in the face of an import duty), or to retain New York as a refining centre, with one-half the product for domestic consumption and only the remainder for export. Two factors must be considered—the relative cost of refining in the two places, and the trade conditions to be met in marketing the product.

In a letter published in the *Canadian Mining Journal* of January 8, Mr. R. W. Leonard argues that refining can be done as cheaply in Canada as in New Jersey. It is difficult to see how such a thesis can be supported. As is well known, the production of nickel from matte involves several successive smeltings with salt cake, whereby the copper-nickel matte is separated into copper containing a little nickel and nickel containing a little copper. Fuel costs at Sudbury almost twice as much as in New Jersey; salt cake costs more than twice as much. We have not at hand any record of the average rate of wages paid at Sudbury and Bayonne, but the average daily wage paid to unskilled laborers in the vicinity of New York is $1.75 to $2 per day, according to figures furnished by the Bureau of Municipal Research. It is evident, therefore, that the labor cost would also be higher in Canada. To abandon refining in New Jersey and take it up in Canada would involve abandoning the New Jersey plant and constructing another in Canada; the cost of the new construction would have to be charged to the cost of refining in Canada, and it is difficult for the outsider to see how costs at the two places could be made anywhere near equal.

Refined nickel produced in Canada, on entering the United States, would be subject to a duty of 10 per cent, or approximately $80 per ton. In order to avoid this duty, one of the two French companies operating at New Caledonia, ships its ore to Holland, where nickel matte is produced that is shipped to New Brunswick, New Jersey, for refining; the refined nickel being sold in the United States in competition with the product of the International Nickel Company. To the unprejudiced outsider it would seem that if the International Nickel Company were obliged to remove its refinery to Canada, and attempt to reach the United States market in the face of a 10 per cent duty, the French company would promptly increase its refinery capacity in this country and supply a larger part of the present demand. It is generally reported that the International Nickel Company has considerable holdings in the New Caledonian nickel region which it has not yet developed. If the French company can operate in the field of an old established company, it seems certain that the International Company would not abandon its New Jersey plant, but would instead supply it with enough ore or matte from its New Caledonia deposits to provide for the consumption of nickel in this country. In attempting to force the refining of Canadian nickel in Canada, it therefore appears as though our friends across the St. Lawrence would be doing something like killing the goose that laid the golden eggs; for it apparently means the abandoning of the United States as a market for Canadian nickel. Turning to the pages of history, we find that when a country has placed an embargo on any of its products, the net result almost invariably has been the ruining of home industry and the benefiting of foreign competitors. It seems probable that a similar result would ensue if the Canadian authorities should place an embargo on the export of nickel ore and matte.

PROBLEMS OF LABOR—II

The testimony given by various persons prominent in public life before the federal Commission on Industrial Relations, sitting in New York during the past week, has been productive of much interest throughout the United States. The statements of such men as Messrs. Jacob H. Schiff, August Belmont, Henry Ford, and John D. Rockefeller, Jr., are worthy of careful attention, since men of such large and wide interests presumably have access to data and sources of information which are not available to the majority. The testimony is too voluminous to undertake to reproduce here even in part, but the statements made by Mr. Rockefeller concerning the labor situation in Colorado, as seen from his viewpoint, are of so much interest to mining men that we give below some extracts.

"The Commission has asked my views as to what extent the stockholders and directors of a corporation are responsible for the labor conditions which exist in it and for the social conditions which are produced; how generally and in what manner such responsibilities are assumed by stockholders and directors; and in actual practice how, and upon what general basis, the labor policies of large corporations are determined.

"The responsibility of stockholders is practically limited to the election of directors. They have no power to elect officers, to employ labor, to make contracts, or to intervene directly in the management of the business. A large stockholder, however, is able to exercise considerable moral influence over the directors and officers, and is responsible for exercising that influence properly.

"The directors are responsible for the general conduct of the business. These responsibilities are in general

divided in such a way that the directors attend principally to the financial affairs of the corporation, leaving the actual conduct of operations to the officers.

"Labor conditions, so far as they are within the control of a corporation, are matters for which the officers of the corporation are primarily responsible and with which they, by reason of their experience and their first-hand acquaintance with the facts, are best qualified to deal.

"Labor policies are initiated and determined by the officers, whose efficiency is largely measured by the harmony and good will which they are able to maintain between the company and its employees. It is not customary to submit labor policies to a board of directors for action. Conference regarding them is often had with the directors or executive committee at the instance of the officers, and suggestions are made to the latter by both these bodies. A business to be successful must not only provide to labor remunerative employment under proper working conditions, but it must also render useful service to the community and earn a fair return on the money invested. The adoption of any policy toward labor, however favorable it may seem, which results in bankruptcy of the corporation and the discontinuance of its work is as injurious to labor, which is thrown out of employment, as it is to the public which loses the services of the enterprise, and to the stockholders whose capital is impaired.

"Anyone who has followed the controversy which has arisen out of the Colorado situation will have observed that no effort has been spared to make it appear that I have attempted to exercise a kind of absolutism over the coal industry in Colorado, and particularly that I have sought to dictate a policy of non-recognition of unions. An attitude toward industry and toward labor such as is here implied is abhorrent to me personally and contrary to the spirit of my whole purpose and training. What are the facts?

"First, with reference to my attitude toward labor unions: I believe it to be just as proper and advantageous for labor to associate itself into organized groups for the advancement of its legitimate interests as for capital to combine for the same object. Such associations of labor manifest themselves in promoting collective bargaining, in an effort to secure better working and living conditions, in providing machinery whereby grievances may easily and without prejudice to the individual be taken up with the management. Sometimes they provide benefit features, sometimes they seek to increase wages, but whatever their specific purpose, so long as it is to promote the well-being of the employees, having always due regard for the just interests of the employer and the public, leaving every worker free to associate himself with such groups or to work independently as he may choose, I favor them most heartily.

"Combinations of capital are sometimes conducted in an unworthy manner, contrary to law and in disregard of the interests both of labor and the public. Such combinations cannot be too strongly condemned nor too vigorously dealt with. Although combinations of this kind are the exception, such publicity is generally given to their unsocial acts that all combinations of capital, however rightly managed or broadly beneficent, are thereby brought under suspicion. Likewise it sometimes happens that combinations of labor are conducted without just regard for the rights of the employer or the public.

"Since we first acquired an interest in the Colorado Fuel & Iron Co. in 1902, the Company has paid out in wages to its employees over $92,000,000. During the same period we have received dividends amounting to $371,000 on our investment in the Company's capital stock. Therefore our stock interest in the Colorado Fuel & Iron Co. has yielded a return of about two-thirds of one per cent per annum on an actual cash investment of about $6,000,000. It should be stated that we hold, in addition to the stocks above mentioned, a block of bonds, but that our entire investment in the stocks and bonds of the Colorado Fuel & Iron Co. has yielded during a period of twelve years not more than 3½% per annum. Yet during that time, instead of exploiting the industry, as has been frequently stated, we have supported a policy of development by devoting surplus earnings to improvements, thereby increasing employment, and generally extending the business rather than paying dividends.

"As to the strike itself, its many distressing features have given me the deepest concern. I frankly confess that I felt there was something fundamentally wrong in a condition of affairs which rendered possible the loss of human lives, engendered hatred and bitterness, and brought suffering and privation upon hundreds of human beings. Without seeking to apportion blame, I determined that in so far as lay within my power I would seek means of avoiding the possibility of similar conflicts arising elsewhere or in the same industry in the future. It was in this way that I came to recommend to my colleagues in the Rockefeller Foundation the instituting of a series of studies into the fundamental problems arising out of industrial relations, which resulted in securing the services of Mr. Mackenzie King, former Minister of Labor of Canada, to direct the studies.

"The strike was called off December 10, 1914. On December 16 Mr. David Griffiths, formerly state coal mine inspector of Colorado, was appointed an intermediary between the Company and its employees respecting matters of mutual interest.

"On January 5 a notice was posted at all the Company's mines inviting the employees at each of the mines to assemble in mass-meeting to select by ballot one representative to every 250 employees in each camp to represent the men at a joint meeting of themselves and the executive officers of the Company in Denver 'for the purpose of discussing matters of mutual concern and of considering means of more effective co-operation in maintaining fair and friendly relations.'

"In the published notice of these meetings it was stipulated that in order that the men might feel the greatest freedom in making their selection they should choose their own chairmen, and neither superintendents nor pit bosses should attend.

"I have received from the president of the Company a telegram informing me that a joint conference was held in Denver on December 19, that the meeting had proved most satisfactory to all concerned and that its spirit had convinced the management that it would lead to more active co-operation between the Company and its employees in the future.

"Thus it will be seen that the Company has already taken steps to initiate a plan of representation of its employees. It is my hope and belief that from this will develop some permanent machinery which will insure to the employees of the Company, through representatives of their own selection, quick and easy access to the officers with reference to any grievances, real or assumed, or with reference to wages or other conditions of employment.

"Capital can defer its returns temporarily in the expectation of future profits, but labor cannot. If, therefore, fair wages and reasonable living conditions cannot otherwise be provided, dividends must be deferred or the industry abandoned. I believe that a corporation should be deemed to consist of its stockholders, directors, officers, and employees; that the real interests of all are one, and that neither labor nor capital can permanently prosper unless the just rights of both are conserved.

"If, with the responsibilities I have and the opportunities given me, I am able to contribute toward promoting the well-being of my fellow men through the lessening of injustice and the alleviation of human suffering, I shall feel that it has been possible to realize the highest purpose of my life."

Entirely transcending the importance of this statement as a thoughtful and fair exposition of the viewpoint of the capitalist on these problems, is the sequel which it bids fair to have. The most bitter opponent of the Rockefeller organization in recent years has been 'Mother' Jones, and her activities in inciting and maintaining strikes are well known. A year ago she endeavored to see Mr. Rockefeller, but was refused admission. At the hearing before the Commission, these two opponents shook hands and made an appointment for a conference on January 27. After the conference was over the two principals made the following statements to the reporters of the daily press.

"John D. Rockefeller, Jr., has been misunderstood," said 'Mother' Jones. "He has been defamed. No one has done more of it than I have. I have denounced him everywhere. Now I am going to do all I can to make that right. I used to call him a 'high class burglar.' I know now that he isn't that. I know what he thinks about these things now. I am sure he means to do right."

"'Mother' Jones," said Mr. Rockefeller, "told me about conditions in Colorado as she has found them. She told me of the complaints of the miners, that they want opportunity to buy their supplies at other than Company stores, that they want schools and churches not owned by the Company, and of which the teachers and ministers are not appointed by the Company officials, that they want the right of free speech and the right to assemble and discuss their affairs; that they object to paying fees for the Company's doctors—a variety of things that they believe to be wrong in principle and practice.

"I found that her mind is remarkably clear. She knows a great deal about those matters that I do not know. I told her that I realized that it was my duty as a director of the Company to know more about them. I assured her that I believed that as a matter of principle the things of which she complained were wrong. Of course, there should be free speech, free assemblage, independent stores, public schools, and all that. We found that on all matters which we discussed we were in agreement.

"I pointed out to her the great difficulty of getting all these things in a mining camp far removed from the ordinary community life where there would not even be an approach to these things if the Company didn't supply them in its own way, the best possible under the circumstances. She told me that she realized the practical difficulties of doing many things which the miners want done. She was very fair and reasonable, and told me that she now believes I am also trying to be fair under arduous difficulties."

The importance of this *rapprochement* between the two persons generally regarded as most typical of labor and capital cannot be overestimated. In spite of the fact that the essential factor in the progress of civilization for centuries has been the struggle for liberty, we are all too prone to overlook this vital element, because of the attention which must necessarily be given to practical details. The simplest analogy which can be drawn is with education.

In recent years, Madame Montessori has emphasized that right education must never restrict the liberty of the child. It is so much easier for a mother to wash and dress her child than to await the outcome of his ill-directed and blundering efforts to do it himself, it is so much easier to show a child exactly what to do and how to do it than patiently to encourage him to do it himself, that parents and teachers restrict the liberty and development of individuality of the child in the mistaken idea that it is necessary to get practical results as quickly and easily as possible. The child is powerless to protest, but the laborer is abundantly able to protest, and has made his voice heard insistently during recent years.

The clearing of the air which must result from the happenings set forth above will almost mark an epoch in the solution of labor problems, and if the labors of the federal Commission on Industrial Relations have no other useful result, they will have been abundantly worth while.

Shaft-Sinking at Kelvin, Arizona

By A. L. FLAGG

These notes are not offered as a discussion of shaft-sinking practice, but rather a description of methods, results, and costs in a single instance in which a three-compartment shaft was sunk 220 ft. from a station, 245 ft. from the surface. This shaft, known as the Westfall, is the deepest and main working exit of the Kelvin-Sultana Copper Company.

The first 245 ft. of the shaft was 'raised,' beginning in a small station cut in the long cross-cut driven to the south from the Diamond Jo shaft to the No. 2 vein. After the connection had been made with the surface, a 60-ft. sump was cut before work was discontinued. There are no adequate records of either progress or costs for raising or for sinking the sump.

After the sump was finished, the shaft was in continuous use for six months from the first or so-called 300-ft. level, to the surface, before sinking was resumed. During that time only a nominal amount of water accumulated in the sump. The timbering, which extended 10 sets below the station, was in good condition, needing no repairs or adjustments. However, before any work could be done toward sinking, it was necessary to enlarge the station, which was exceedingly small and ill adapted to use as a point from which to sink.

FIG. 1. HEAD-FRAME AND HOIST-HOUSE.

The rock in which the shaft was sunk is a fine grained greenish black diabase, tough, though locally often extensively shattered. Throughout the entire mass are three sets of joint planes. The strike of the strongest of these is nearly at right angles to the longer diameter of the shaft. The dip is normally 52° to the south. This condition usually kept the south end of the shaft in advance of the north end, though there were times when local irregularities in the dip would cause the opposite condition to prevail. The other two series of joints exerted little or no influence on the breaking of ground.

While the camp is not a mining centre, it is not far from some old established places. Even so, it was not always possible to secure skilled labor on short notice. During the time sinking operations were in progress the Company was able to keep two full crews of excellent shaft men. Only white men were employed, though in other parts of the mine, Mexicans are generally employed. Each crew consisted of a 'jigger,' three miners, and a top-lander. At the outset these men were paid $4.50, $4, and $3.50, respectively. Later, when more water was encountered, the rate was increased 50c. per man. This rate was paid until shaft work ceased.

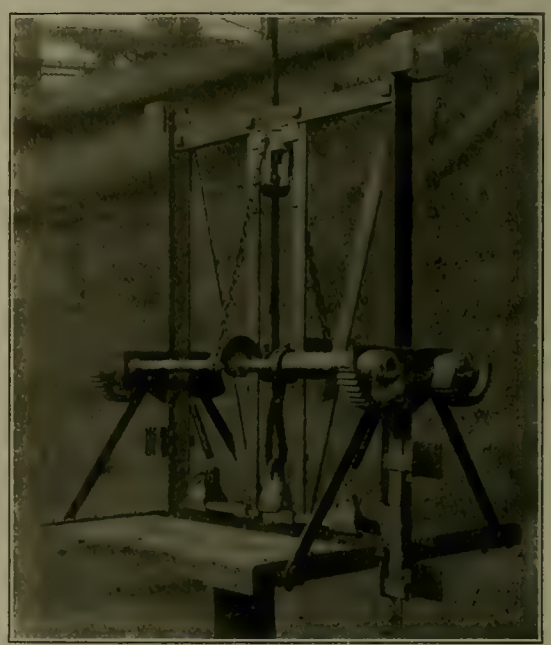

FIG. 2. UNION SAFETY CROSS-HEAD.

Hoistmen operating the sinking engine received $4 per day.

The advantage to be gained by having plenty of light for the men to work by was not overlooked. Throughout the rest of the mine the Wolf acetylene lights are used. In the shaft four 40-watt Mazda lamps, provided with suitable guards, gave abundant illumination. The lamps were spaced at four-foot intervals on twisted strands of No. 14 rubber-covered double-braid wire, which was protected by extra heavy loom. This could be hung in any desired position, and when necessary, as in case of shooting, the end could be hooked to the bucket, and the whole drawn up out of the way. The line was carried down the man-way, paid out from a reel as the shaft progressed.

Sufficient ventilation was provided by a No. 5 Buffalo electrically-driven blower. The air was transmitted through a 10-in. galvanized pipe, with suitable connec-

tions at the blower to permit of using as an exhaust to draw gases out after shooting. The pipe extended to the surface, insuring a positive disposal of the gases as well as pure air when blowing. Fifteen minutes was generally enough to clear the atmosphere after a blast.

Sinking was done from the centre compartment, 'muck' being hoisted to the station by means of a $3\frac{1}{2}$ Vulcan steel-frame hoist, having a capacity of 3500 lb. at a rope speed of 285 ft. The hoist was operated by a 30-hp. 3-phase, 60-cycle, 440-volt motor, with solenoid brake and safety device to prevent overwinding. The capacity is 6900 lb. at a rope speed of 360 ft. per minute, using a one-inch rope.

On arrival at the surface, waste was trammed to the dump by one top-lander, who took care of the combined output of the mine development work. The average distance trammed was 60 ft.; maximum distance, 108 feet.

The buckets were 40 in. high by 27 in. wide, with a

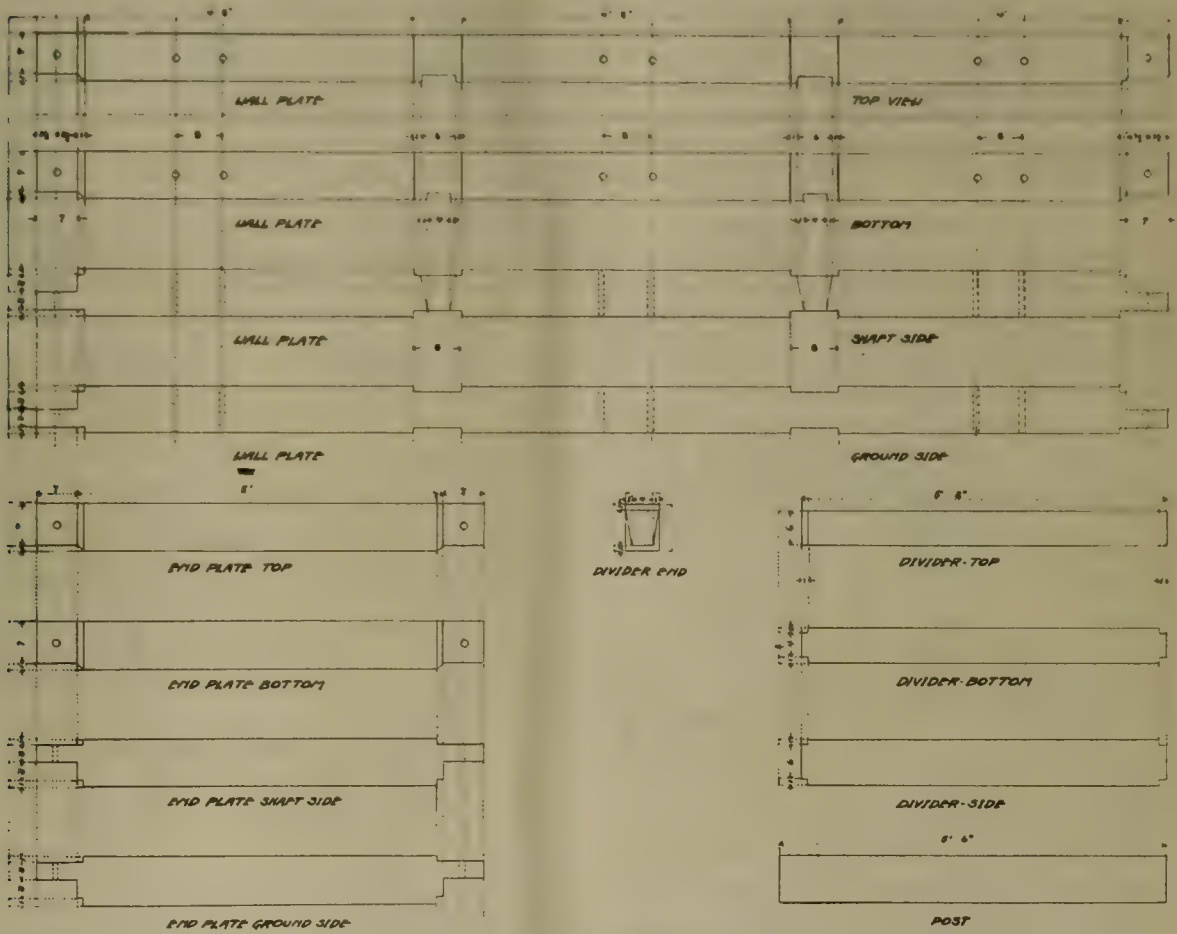

FIG. 3. METHOD OF FRAMING TIMBER.

General Electric 3-phase, 60-cycle, 440-volt motor at 1135 r.p.m. full load. The ¾-in. cable was used.

The rock was dumped directly into 16-cu. ft. end-dump cars, which were run on landing doors. The cars were then pushed over the turn-sheet to the next compartment south, through which they were hoisted to the surface on a single-deck steel cage, weighing 1600 lb. This compartment was also the outlet for all development work on the 300-ft. level, but in all instances preference was given to shaft work. Little or no congestion was experienced except when timbers were being lowered, and then only for short periods. The surface hoist is a double-drum, electric machine designed to operate in counterbalance, though only one side could be used during the period of sinking. The hoist is equipped with a 75-hp., $3\frac{1}{2}$-in. belly. The style of cross-head used, as illustrated, was found quite satisfactory, and proved an economical investment.

The shaft is of three compartments in a straight line, 6 ft. 4 in. by 16 ft. over all. The two hoisting compartments are 4 ft. 8 in. by 5 ft. The third compartment or manway is 3 ft. 11 in. by 5 ft. in the clear. This compartment carries air and water lines, a 10-in. ventilating pipe, and wires for power, light, and telephone, all of which are enclosed in conduit.

The shaft sets were spaced at six-foot centres. The wall-plates, end-plates, and posts are 8 by 8 in. The dividers are 6 by 8 in., and guides 6 by 6 in. Two-inch material was used for lagging. Oregon pine was used throughout, it being found more satisfactory, though of

slightly higher first cost than native pine. All framing was done by hand, one framer and a Mexican helper turning out a set a day with the necessary blocking and lagging.

Details of framing the sets are shown in Fig. 3. Shooting timbers were cut from round, peeled, native pine poles, 6 in. diameter at the top and 15 in. at the butt. The longer ones protecting the wall-plates were suspended by bolts in two parts, joined together by welded eyes making a flexible coupling. One end of the bolt was passed through the shooting timber, and left in place during the life of the timber. The other end was passed through the regular hanger-bolt holes in the wall-plates. The shorter timbers protecting the end-plates and dividers were laid across the longer timbers, then brought into place by tension on the bolts mentioned.

For aligning the sets as they were placed, the usual method of using small blocks $\frac{1}{8}$ in. thick was employed, the line centring one inch from the corner each way. As the timbers were framed, the carpenter marked with his scratch-awl a line one inch from the corner on end-plates and wall-plates, which facilitated lining up. New blocks were placed every third or fourth set.

In the original shaft, 4 by 6-in. guides were used, behind which were placed one-inch fillers. In the new work 6 by 6-in. guides, without fillers, and dapped out one inch, were used. The method of making the joint is

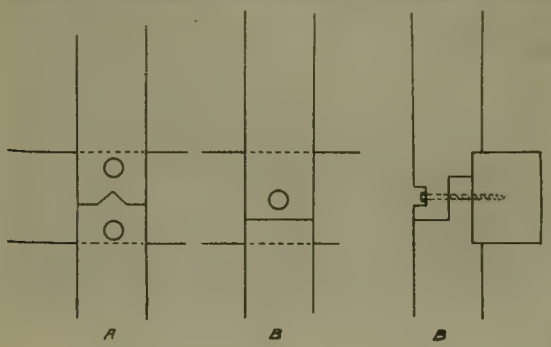

Fig. 4.

shown in Fig. 4. The original joint (*a*) was not found satisfactory; the style (*b*) used below the 300-ft. level has been found to be more secure, besides being more quickly made.

Whenever possible, timbering was done from the top of the 'muck' pile, the last set, as a rule, being less than 20 ft. from the shaft bottom. The timbers were lowered in the usual manner by clevises. For swinging the wall-plates into place preparatory to inserting the hanger-bolts and blocking, a simple but efficient device was used. It consisted of two lengths of $\frac{1}{2}$ in. steel hoisting rope, 22 ft. long. One end of each was looped through a strong welded iron ring and fastened with clamps. The other end was slipped into a piece of $\frac{3}{4}$-in. standard black pipe 14 in. long, and securely fastened by means of babbitt metal. To the bottom end of the pipe was fitted a $\frac{3}{4}$ by 2-in. reducer. The loose ends of the cables were passed through the hanger-bolt holes in the wall-plates of the last set, then through the holes in the wall-plate to be hung, and reducers screwed on. The ring was then attached to the hoisting cable, which easily and quickly drew the wall-plate into place.

Except for the first few rounds, Sullivan UE-2 ($3\frac{1}{8}$-in.) piston-drills were used throughout the shaft work. The machines were mounted on cross-bars $5\frac{1}{2}$ in. diameter by 6 ft. long, which were lifted into place by the hoist as they were lowered. For holding the bar in place, while it was being blocked, a support was made of 2 by 12 in., about 5 ft. long, having a V-shaped notch cut in one end. Cleats were nailed on one side of this support, which was used later by the drill runners to stand on while drilling.

Air at 90 lb. pressure was maintained whenever possible, though owing to the limited capacity of the compressor this often fell below an economical working limit. The number of holes drilled for each round was 24. The average total drilled per round was 166.5 ft. The placing of holes is shown in Fig. 5. The total foot-

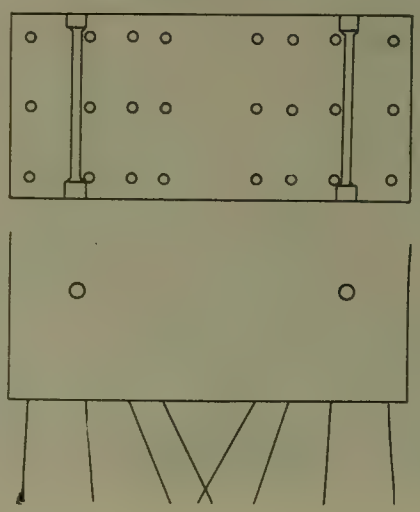

Fig. 5.

age drilled was 5828. The steel consumption was 383.48 lb., or 0.0658 lb. per foot drilled, costing 16.3c. per foot of shaft.

Each set of steel consisted of five pieces, ranging in length from starters 2 ft. 10 in. to finishers 12 ft. long, with a difference of approximately 2 ft. between successive drills. Beginning with a $2\frac{1}{2}$-in. bit on the starters, each succeeding bit was $\frac{1}{8}$ in. less in diameter, the finishing bit being $1\frac{7}{8}$ in. One and one-eighth octagon steel, with a $\frac{1}{8}$ by $4\frac{7}{8}$-in. shank at one end, was used. On the other end 2 ft. of ribbed steel was welded, the latter being $1\frac{3}{4}$ and $1\frac{3}{8}$ inches.

Cut holes were drilled from 10 to 11 ft. deep. Back holes were from 7 to $8\frac{1}{2}$ ft., depending on the ground. The cut holes sometimes crossed, at other times lacked a few inches of coming together. The bars were set up 3 ft. from the ends of the shaft, and 4 ft. 10 in. above

the collars of the breast, and back holes. The collars of the latter were in line with the end-plates. The shaft was broken about 8 by 17½ feet.

The average charge per round was 105 lb. of 1¼×, 40%, Hercules gelatin powder. For the first seven rounds 7/8-in. sticks were used, but were found quite unsatisfactory. Owing to an irregularity in one consignment of powder, it was found advisable to fire the cut holes first, then after 'mucking' out, fire the rest of the round. As this practice was in force only for a few rounds toward the last, it is impossible to say whether there is any real advantage in this system, though there were certain indisputable evidences of increased speed with no appreciable increase in costs.

At no time was the amount of water sufficient to justify the installation of a pump, though considerable bailing had to be done. The water was bailed into the sinking buckets with pails, and hoisted to the 300-ft. level, where it was dumped into a special wooden-body water-car. The car was pushed into the main cross-cut to a point about 70 ft. from the shaft, and the water let out through a trap to flow to a sump from which it was pumped to the surface. One of the notable features of the work was the small number of misfires. In the shaft work proper, 35 rounds of 795 holes were fired, and there were only six misfires. While no records are available as to the number of misfires in previous work, it is known that they were numerous. The small number of misfires is attributed to the use of 'delay action fuses' manufactured by the California Cap Co., which is nothing more or less than an electrical device for spitting fuses. The use of such fuses has already been well described in the technical press.* The method of connecting terminals, Fig. 6, was somewhat different from

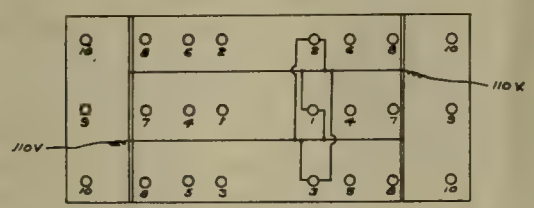

FIG. 6.

that described in the article referred to. Two pieces of scrap timber, usually broken lagging, were placed a few feet from the ends of the shaft, and securely wedged in place. From these, two strands of ordinary hay bailing wire were stretched about four feet apart. The terminals of the fuses were connected to these, which in turn were connected to the shooting circuit, the switches of which were under lock and key, accessible only to the foreman. The numbers in the diagram refer to the order of firing.

As the shaft reached the point where the station was to cut, the initial rounds were drilled. This work is not taken into account in making the estimates of costs. Below the shaft a sump 29 ft. deep was cut.

The station on the 500-ft. level is 14 ft. 8 in. by 35 ft. in the clear, 18 ft. high at the shaft, and 10 ft. high in the back. Under the station, set bearers 16 in. square by 10 ft. long were placed in hitches 2 ft. deep. There are no bearers at the level above. Regular sets begin again directly under the bearers. Back of the station proper is a pump station 15 by 20 ft., 10 ft. high, with a sump having a capacity of 25,000 gallons.

The total number of shifts worked was 218. Of that number, the first seven were occupied in bailing out and 'mucking' the last round fired in previous work. Seven more shifts were given to making alterations and adjustments, caused chiefly by the breaking of the hoist motor. The total number of shifts occupied in actual sinking operations was 204.

The following table shows the costs:

LABOR			
Shift boss	$ 992	Ventilating	18
Drilling	1,105	Timber framing	708
'Mucking'	1,422	General expense (foreman)	654
Hoisting	1,081	Administration	140
Compressed air	44	Survey	24
Blacksmith	313		
Timbering	604		
Draining	56	Total	$7,161
MATERIAL			
Powder	$457	Air pipe	69
Detonators	54	Ventilating pipe	64
Fuse	2	Miscellaneous fittings	23
Carbide	2	Timbers	1,182
Lubricating oils	7		
Steel	36	Total	$1,896
MISCELLANEOUS			
Power	$1,243	Drill depreciation	19
Taxes and insurance	17	Miscellaneous tools	179
Drill repairs	141		
		Total	$1,599
Grand total			$10,656
Cost per foot			$48.43

MINTS in New South Wales, Victoria, and Western Australia transacted the following business in 1914:

Ore Treatment by the Vandercook Process

By E. C. MORSE

*The apparatus used is simple in both construction and operation, and along lines sufficiently new that the owners have been able thoroughly to cover their apparatus and methods with patents in the United States and several foreign countries, and to obtain a basic patent on their filter.

In the process to the tube-mill, nothing new is claimed. Any standard method of crushing, such as rolls preceded by rock-breaker, if the ore be soft, or stamps preceded by a crusher where the ore is hard, may be used. The tube-mill practice varies according to the peculiarity of the ore.

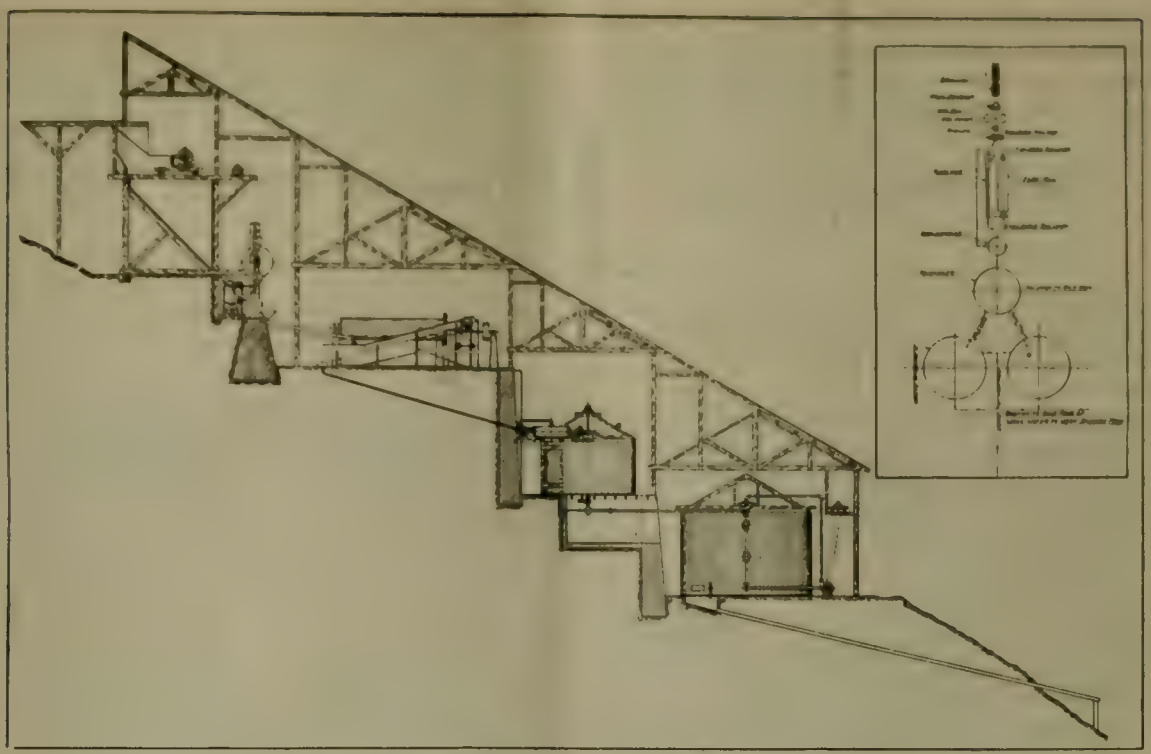
The first device of note is a classifier. Its chief distinction is its extreme simplicity, being designed so that wearing parts can be instantly replaced, and so that its speed can be readily changed according to requirements. While there are some small details that differ, it is roughly a combination of a hydraulic classifier with the Esperanza principle. Endless chain drags are employed to elevate the sand out of the bottom of the cone or hopper and up an incline, from which it is delivered to the scoop feed at the head of a tube-mill, without the use of any other elevator or pump. This classifier is admirably adapted for tube-milling arrangements where it is desired to deliver the ground product of the tube-mill into the cone, allow the finished slime to overflow the weir, and pull the ground sand up a slope to the head of the mill, thus eliminating wet elevators from the grinding and sliming system.

After the ore is slimed it passes to an amalgamator designed as follows: It consists of a 10 by 4-ft. tank with an iron bottom resembling an amalgamating pan, and a Vandercook agitator fed from above. This agitator resembles a lawn sprinkler in its action. It consists of a grit-proof bearing with extended hollow arms, fitted with staggered nozzles and revolves backward by reason of the impact from the discharging nozzles, which are supplied with the solution pressure which actuates them by a large-sized slow-speed centrifugal pump. In the standard units that are made, this apparatus is absolutely dependable, and the manner in which it keeps the bottom of the pan clean is remarkable. On the bottom of this pan is about one flask of mercury, or 75 lb. This continuous agitation of the pulp in cyanide solution in the presence of mercury serves two purposes. Any coarse gold that is clean, and would otherwise be slow to dissolve in the cyanide solution, is recovered here by amalgamation in the same manner as in pan-amalgamation practice. The other purpose which the mercury serves is the desulphurizing action, freeing the solution from alkaline sulphides. According to my tests it also aided in a remarkable degree in the extraction of silver in the ore, as this metal was nearly all extracted from the ore in the amalgamator, while in the ordinary practice in mills at present in operation in Republic the dissolution of the silver is very slow. This agitator operates so slowly that there is no tendency to the flouring of quicksilver, and yet the surface of the mercury is kept clear from accumulations of every sort. This amalgamator is operated continuously, pulp flowing in and going out by overflow.

The pulp from the amalgamator passes to a thickener, driven by worm gear, and using a vat of suitable proportions for the desired tonnage of a given ore. It differs radically from the older thickeners in its internal arrangement. It is provided with rakes of spiral form, well supported and stoutly built, and so arranged as to squeeze the moisture out of the pulp before it is discharged, whenever it is desired to do so. This machine should take less than 1 hp. to operate a tank 30 ft. diameter. When desired, the material can be thickened so as to contain only 30% moisture when it is discharged on a belt, should this be necessary. Such would not be done, however, in ordinary practice. The overflowing solution from this thickener is returned to the storage tank to be re-used in grinding and classifying. The thickened material, which is discharged from the bottom, goes to one or the other unit of the agitating and filtering plant.

The agitating and filtering plant is really the important part of this system. It consists of a steel tank with a Vandercook agitator, similar to the one described on the amalgamator, but of larger size. It has a canvas filter-bottom of about the same design as an ordinary sand-leaching vat, and is supported by burlap and woven wire stretched across a grating. The canvas is held in place by rope corking as usual. The charge of pulp and solution is agitated in this tank during the operation of filling. When it is full, treatment commences. During the action of the agitator the canvas is automatically kept clean so that solution can readily filter through it. When vacuum is applied by a centrifugal pump, the filtering operation becomes rapid. During the agitation the pregnant solution is continually drawn from the filter through the canvas bottom by either natural filtration or the aid of a vacuum, and barren solution continually replaces it, so that the agitator during its operation removes the gold and silver as fast as they are dissolved, sends them to the zinc-boxes, and constantly replaces them with barren solutions from the boxes. This combined filter and agitator can be applied with advantage in a great number of places whenever slime or finely pulverized sand is dealt with, but it is not claimed that it could be successfully

*From a report on the process as tried on ore from the Hope mine, Republic, Washington, at the California Extraction Co.'s plant, Oakland, California.



VANDERCOOK SYSTEM OF ORE TREATMENT.

used on sands coarser than 80 or 100 mesh. It is equipped so that the following operations can be carried on: agitation, aeration, and continuous displacement. It is also equipped so that filtering can be carried on by gravity, pressure, or by the application of vacuum.

The vacuum-pump, receiver, and unloader devices have received considerable attention in order that they might be simple to operate and repair, and repair parts are all standardized, so that repairs and renewals can be obtained from almost any machinery supply house. In fact, that has been the aim in designing the whole equipment. This filter is also an excellent clarifier. The solutions come from it as clear as could be desired for a zinc-box precipitation.

The California Extraction Co. has a basic patent on this filter, the novel feature being that it is the only filter that accomplishes its filtering operation without the building of a cake. On first consideration, metallurgists who have been accustomed to that type of machinery will be prejudiced against it, because of its similarity in appearance to the other machines that have not given entire satisfaction; still that prejudice must disappear when it is remembered that the plant described never gave trouble when operated intermittently, and when there was no chance for the building up by accumulation of the relatively coarse sand, thus stopping the machine. And, of course, the Vandercook machine is discharged at the end of each cycle, so that no accumulation can take place.

The objection to centrifugal pumps can readily be overcome by the installation of two of them with each machine. The strongest point in favor of this system is the small amount of tankage that it will require. Aside from the solution in storage, an amalgamator, and a thickener 12 by 32 ft., will constitute all the tankage necessary for a 200-ton plant. The objection to most modern cyanide plants is that they are spread out over too much ground. The compactness of the Vandercook arrangement is much in its favor. Any finely pulverized ore that will yield to cyanide treatment in any machine for cyaniding will give up its soluble metals in this machine, so that the exact results obtained in these tests are of only secondary importance to me. Any objection that exists to this machine mechanically, exists to a greater degree to a popular displacing machine, and the machine in question has made such a marked success that it has been installed in several mills as an aid to filters, and in some in place of them. This has been notably the case in some of the mills in Nevada, particularly around the Comstock lode.

In discharging the Vandercook machine after it finishes the cycle of treatment, a water wash is applied and the pulp reduced to 40% moisture. Then the charge is sluiced by any available means.

The zinc-boxes employed in the Vandercook system also deserve special mention. There is nothing new in principle about them, but they are designed so as to be handier to clean up and pack. They are cone bottomed and made large enough so that comparatively few will be required, and so arranged that the precipitate can be drawn from the bottom into a filter or

dryer and the handling of zinc is reduced to a minimum.

In the tests on Hope ore assaying $5.37 gold and $2.20 silver per ton, 95.7% crushed through 200 mesh, and treated in the plant described, the extraction was 97.7% of the total value. No lead acetate was needed at all, lime consumption was 8 lb. and cyanide 0.6 lb. per ton, a satisfactory result. The Republic ores were described in the *Press* September 19 last.

New Filtering Process at the Treadwell Cyanide Plant

By W. P. LASS

Among the more recent developments at the concentrate cyanide plant of the Alaska Treadwell Gold Mining Co. that have tended to lower operating costs and increase the extraction, has been the adoption of the Treadwell self-sluicing drum type of filter-press.

The original equipment of filters consisted of two type 1B 50-ton Kelly filter-presses. The principal objection to these was the labor in operating and repairing. It was accordingly decided to build a self-sluicing drum type of filter. Two of these presses have now been in continuous operation for the past nine months, one for clarifying solutions, and the other for filtering concentrate. Their complete success has improved greatly the efficiency of the whole plant. The plant, which formerly required two men on each of the three shifts to discharge 100 tons of material and clarify 800 tons of solution, is now being operated on two shifts by part of the time of one attendant. However, it is not only the operating labor, but the upkeep and repair costs that have been materially reduced.

The filters are closed during the whole of the filtering operation, in fact, they may go for weeks without being opened, and the attendant has only to manipulate the valves. Waste of solution is reduced to a minimum, and the appearance of the plant greatly improved.

The accompanying illustration shows the filter as used at present. It consists of a steel cylinder 8 ft. diameter and 16 ft. long, lined on the inside with concrete, to form a square box to receive the filter-leaves, without leaving void spaces which would require a larger amount of excess pulp or solution in the operation of filling or discharging. The filter was made round as the simplest and most economical means of obtaining the required strength. The heads of the press are boiler plate, reinforced with I-beams to withstand a pressure of 200 tons.

The filter-head is only removed when it is necessary to change leaves. The filter-frames are 16 ft. long and 5 ft. high, made of flat strips of spring steel ¼ by 1¼ in. These are run in by means of rollers and guides fastened into the bottom of the press.

A 1-in. pipe at the bottom of each leaf, for the outlet of clear solution, is run through a hole at the far end of the press, and sealed with gummets and lock-nuts; after all the leaves are in place the heads are bolted on, care being taken to clean the gasketed end of the press from foreign matter that would cause leaks when the pressure is applied.

The apparatus now being closed, the pulp or material to be filtered is allowed to flow into and fill the press by gravity from the pulp tank situated 30 ft. above. An escapement valve on the top of the press is used to relieve the air pressure until the machine is full, when this valve is closed, and the discharge cocks from the filter-leaves are opened for a sufficient length of time (from two to four minutes, depending on the gravity of the pulp) for the formation of a 1½-in. cake on the leaves.

After the desired thickness of pulp has been deposited, the discharge cocks are closed, and the excess pulp emptied from the press by admitting compressed air into the top, driving the pulp back to the original pulp storage tank referred to above. The valve on the pulp-line is then closed, and either a treatment solution or a wash-water run in just as the pulp was admitted, by allowing the escapement valve on the top of the press to open, and thus by lowering the pressure to admit the solution which comes in under a lower pressure than is maintained by the compressed air.

When the press is full, as shown by a pressure gage, the operator closes the escapement valve and opens the discharge cocks, thus allowing the solution to percolate through the cake deposited on the leaf for either treatment or filtering purposes.

In this manner as many treatments or washes as desired may be given to the cake, while still on the filter-leaf. At the conclusion of the wash, the solution is blown back with compressed air, and the discharge cocks opened for drying purposes. By this means the moisture in the cake is reduced to 8%, when it is ready to be discharged.

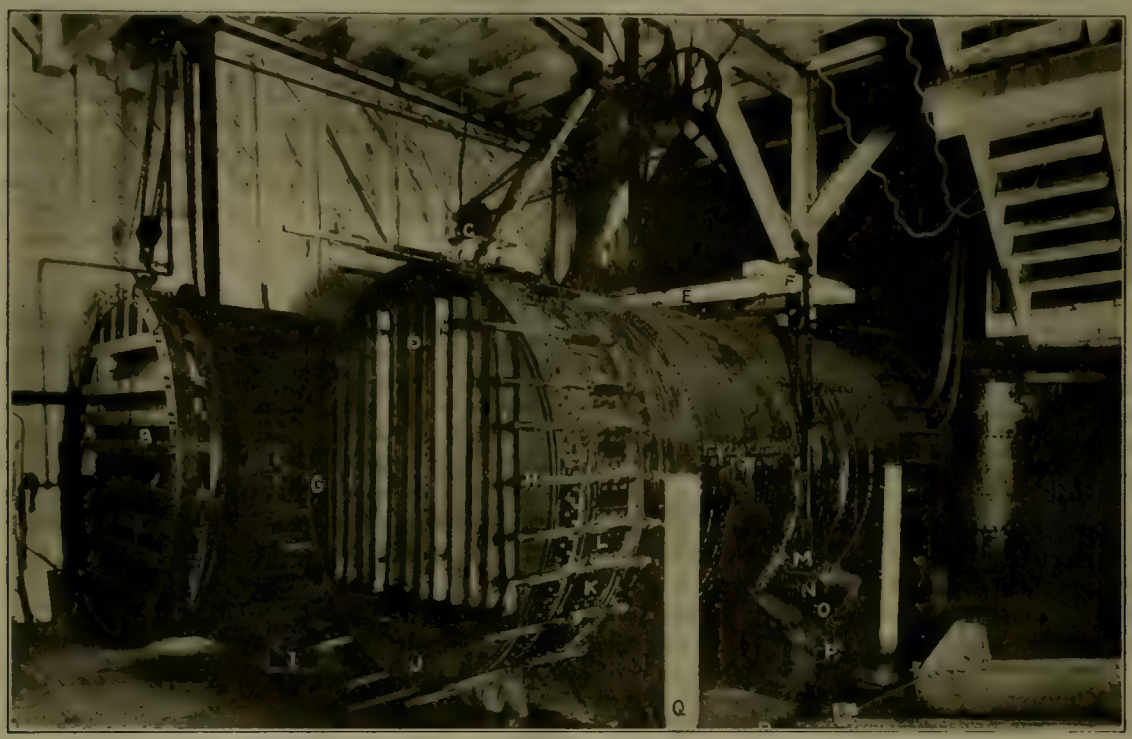
Water is now turned on through a revolving spray-pipe, operated by an electric motor, and running through the under side of the press in such a manner as to wash off the cake and sluice out the residue through the 6-in. pipes leading from the lower side at each end of the press. The time of operation of a complete cycle is 100 minutes. The time allowed to take off the head of the press, remove the old leaves and place a complete set of new ones ready for operation, is four hours or one-half shift, although, if occasion demands, the press may be 'dressed' in less than two hours.

One of the important advantages of this self-sluicing press is that it may also be used as a treatment press, and under certain conditions may entirely dispense with agitation or treatment tanks. Sand deposited on the filter may be given acid washes, alkali treatment, aera-

tion, cyanide treatment, or water washes, without removing the cake from the filter leaves.

No pumps are used in connection with this filter, and the absence of any vacuum is one of the important features. The simplicity of the apparatus makes the construction costs compare favorably with any press of equal capacity.

Instructions posted in the plant for the operation of the Treadwell self-sluicing drum-filters are as follows: (1) Under no conditions allow pressure on filter tank to exceed 45 lb. per sq. in. (2) In order to make a pulp cake in the Treadwell press, it is first necessary to have from 45 to 50 tons of pulp in the pulp storage tank. (3) At 30 to 32 lb. pressure, which 50 tons of pulp in the tank gives, it takes an average of 7 minutes to fill the press. (4) During filling, the cocks in the front of the press are to remain closed, and then be opened as soon as the press is full. By doing this, a uniform cake is made when filtering. (5) Do not allow press to fill suddenly, but by means of the relief valve let air out gradually; when nearly filled, maintain air pressure at 25 lb. to prevent knocking. (6) The condition of leaves, as regards the time they have been in the press and the specific gravity of pulp, has to be considered in forming a cake. (7) Better results are obtained all round, especially as regards tailing, if the cake is not made too thick. (8) A space between each leaf is really necessary, in order that the wash be filtered through each side of the cake. (9) When it is time for filtering, the cocks are closed, and the air is turned into the press from a convenient valve, to blow back the excess pulp in the filter. From 15 to 20 lb. of air above pulp pressure will be plenty for this purpose. (10) The gage on the press indicates what is going on, and as soon as the pressure starts to decrease, if working the press alone, turn off air about half, close the valve opened first, and then the others in turn. (11) While leaves are new, pressure will not exceed 15 lb. per sq. in. (12) It is at no time necessary to wash at more than 30 lb. pressure. (13) A 20-min. wash is sufficient. (14) Excess wash water is returned in the same manner as pulp, using, of course, the proper lines. When this excess is returned, drying is commenced immediately, at about 15 lb. pressure, gradually bringing it up to about 20 to 25 lb. (15) Drying for about 20 min. has been found sufficient, but whether more is to be given will depend on prevailing conditions. (16) The air is then let out of the press, and the cake is ready to be discharged by the sluicing system. (17) In the centre of the bottom of the press is a water connection with a 1¼-in. nozzle pointing toward each end. As soon as possible after opening the 4-in. valve discharge, one at each end of the press, open water valve, in order to keep discharge valves from plugging by the cake dropping. (18) No harm can be done by opening this valve wide. (19) To remove the cake from leaves, a



FILTER PRESS AT THE TREADWELL MINE. A, CRANE; B, HEAD REMOVED; C, MOTOR DRIVE TO SLUICING BARS; D, FILTER LEAVES; E, SHAFT; F, CRANK; G, H, J, CONCRETE FILLING; I, DISCHARGE VALVE; K, L, BOLTS; M, RACK; N, PINION; O, SLUICING PIPE; Q, R, S, WOODEN SUPPORTS.

2-in. drill bar, with nipples attached, so as to come between each leaf, runs through the press ¼ in. below the bottom of the leaves. This bar is supplied from both ends with water, at about 60 lb. pressure. (20) By means of a worm and gear, attached to the bar outside of the press, and having shaft running to a motor, it is kept moving in a circle in order that the high pressure of water will not damage the leaves, and also to facilitate the discharging of the cake. (21) As regards samples, the man in charge will instruct the press operator when and how he requires them taken. (22) Inspect 6-in. sluicing-out pipes for leakage when filling the press.

[An application for a patent for this press has been made, but so far as Mr. Lass is concerned he is quite willing to allow its being used by any millmen.—EDITOR.]

The Ladd Manganese Mine

By SAMUEL H. DOLBEAR

MOUTH OF ADIT 600 FT. LONG, 300 FT. BELOW TOP OF VEIN.

By far the most important source of manganese ore in California has been the mines of the Livermore-Tesla district in Alameda county. A number of properties have been worked in the past, the largest producer being the old Ladd mine.

Interest is again centred in this property through its sale recently to the Western Manganese Co. of San Francisco. The sale brings to mind its history, and the circumstances which surrounded its closing down in 1902. It has been the general impression, I believe, that the ore reserves were practically exhausted, and that its period of activity had passed.

Justinian Caire was the owner some 20 years ago, when the largest shipments of ore were made. The output was largely taken by chlorinating plants. When this process of treating ores gave place to other methods, Mr. Caire sold the mine to the Treadwells. Since that time, the mine has been closed down, and no ore produced except in a small way by occasional lessees.

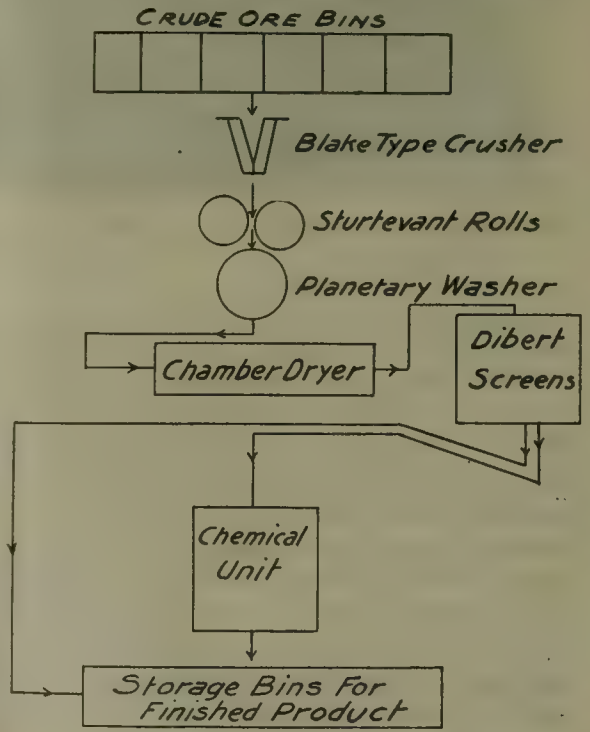
One of the significant factors in this purchase is that the Western Manganese Co. was not the only bidder for the mine. This may be taken to indicate that there is more than a casual interest being shown in manganese at this time.

The Looraine Mining Co. was formed and became the owner of the property. It appears that the most of the stock of this Company was pledged as collateral with the now defunct California Safe Deposit & Trust Co., the trustees of which effected the recent sale.

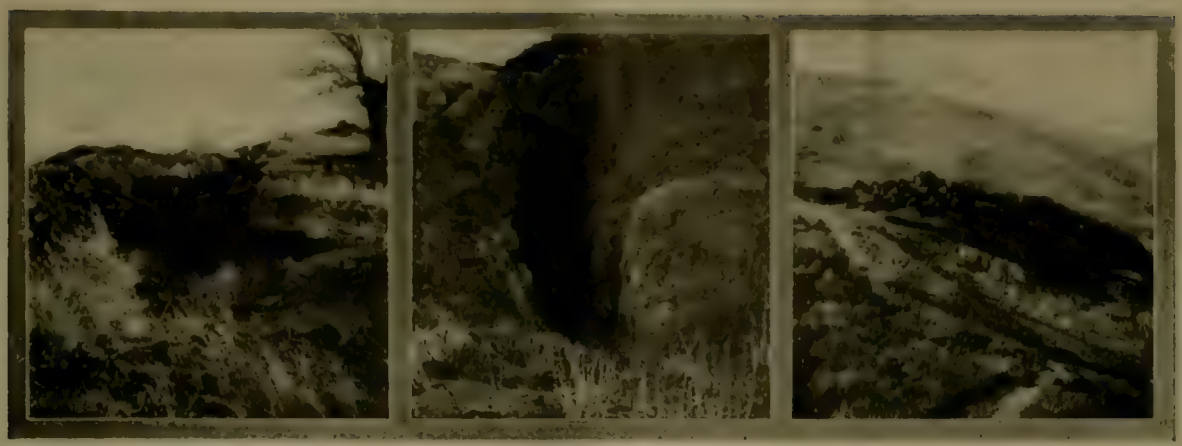
The principal workings of the Ladd mine are reached by a cross-cut about 600 ft. long. This was carried considerably beyond the point at which it cut the orebody, presumably in expectation of finding other deposits of manganese. Stopes have been run to the surface, a distance of about 150 ft. Other than from the main workings, some ore has been mined by making open-cuts on the vein where the contour would permit easy mining. Some of the workings may be seen in the accompanying illustrations.

In the foregoing, it will be noted that I have referred to this occurrence of manganese ore as a vein. E. C. Harder, in his report, says: "The deposit appears to be a filling of a fault fissure between walls of solid rock, and is exposed along the strike for several hundred yards, in which distance it varies considerably in thickness, but averages about four or five feet. It has a strike of about north 80° west, and a dip varying from 45° south to nearly vertical. Smaller veins branch off from the main fissure at low angles and continue for short distances in the wall rock."

The ore is described by Harder as manganite, but such a determination does not conform to recent analyses made for the Western Manganese Co. These analyses would seem to show that the ore is largely pyrolusite with some manganosite, and only a small percentage of manganite. The percentage of combined water is too small to indicate the presence of much psilomelane. The following analysis has been furnished



FLOW-SHEET AT THE LADD WORKS.



LADD MINE OF WESTERN MANGANESE CO., SHOWING OUTCROP OF ORE AND SURFACE WORKINGS.

by the Company as characteristic, and is intended to represent the average grade of ore to be found here:

Minerals.	Per cent.
Mn	48.28
MnO_2	62.10
MnO	18.00
Mn_2O_3	0.30
Fe_2O_3	0.30
Al_2O_3	1.00
SiO_2	8.70
Sulphur and phosphorus	trace
H_2O (combined)	4.40

The principal impurities in this ore are to be removed by treatment in the Company's recently constructed plant at Alameda. A description of this plant and its operation was detailed in the *Press* of January 30. The general method of treatment is shown in the accompanying flow-sheet.

Adjoining the Ladd mine is the Winship-Doak property, which is along the strike of the fissure. As little ore has yet been taken from the latter, the ground is almost intact. Recently a re-survey of this area established the fact that the boundary between the two properties had been marked in error, with a resultant gain to the Western Manganese Co. of nearly 300 ft. of virgin ground. The ore possibilities in this addition are pretty clearly indicated by the old stopes, and insure a considerable tonnage. Operations are to commence here as soon as the sale has been confirmed by the court. In the meantime, the Company has contracted for the entire output of the Winship-Doak mine.

THE BRADEN MILL, Chile, in November treated 83,703 tons of 2.13% copper ore, yielding 6935 tons of concentrate. The Minerals Separation plant treated 82,027 tons, producing concentrate assaying 19.94% metal. The copper output was 2,404,000 pounds.

NEW SECURITIES listed on the New York Stock Exchange in 1914 totaled $671,864,800, against $874,102,000 in 1913, and $1,816,009,000 in 1912, and $2,410,000,000 in 1909.

A Substitute for Danish Pebbles

*As a part of the Boise project, Idaho, the Reclamation Service is building the Arrowrock dam, a masonry arch, 350 ft. high. One of the notable features of this work is the use of sand cement instead of the portland cement. A sand-cement plant was erected at the dam and a finely ground 'blend' made of, roughly, 50% each of portland cement and rock obtained near the site. For this grinding tube-mills are used, and at first the general practice was followed of using imported Danish flint pebbles in the mills. The price of these pebbles plus freight amounted to $26.25 per long ton at Boise.

Dissatisfied with this cost, the engineers looked for a substitute. At first, pebbles found near the dam were used, but these proved unsatisfactory. Then lava rock chunks of roughly cubical form were tried, which have proved highly successful. After a few hours in the mills the angles are worn off and the pieces assume a shape like the ordinary pebble. They are considered to be equal or superior to the Danish pebbles, as they are heavier, break up less, and wear longer.

A plentiful supply of lava rock pieces was found along the government railroad built to the dam, where slides have broken the rock into pieces of the desired size. These slides are mostly on government land within 15 miles of the dam, and the pieces are picked up, sacked, and put on the railroad at a cost of about $2 per ton, including about 50c. for the sacks, which quickly wear out. There is thus saved about $24 per ton, or 90% of the cost of the Danish pebbles.

The supply of lava chunks along the railroad between Boise and Arrowrock is considerable, and it is possible they may find additional and larger markets If the less accessible lava slides were thus utilized, the cost would probably be increased somewhat over the above figures, but there are large quantities within easy reach of the government railroad.

---

*Abstract from the *Reclamation Record*, Feb. 1915.

Specific-Gravity Apparatus

By J. M. LILLIGREN

Specific-gravity determinations are necessary and frequently made in the different departments of all cyanide plants. Convenience and rapidity are essential where a number of such tests are made each shift; also, protection of the apparatus used against breakage, and particularly the getting out of order due to rough and careless handling are important.

The accompanying sketch shows the apparatus in use at the Aurora Consolidated Mines Co.'s plant, Aurora, Nevada. The scale is a standard make of the spring type, is adjustable, and has a capacity of 24 lb. The original dial is graduated to pounds and ounces. A

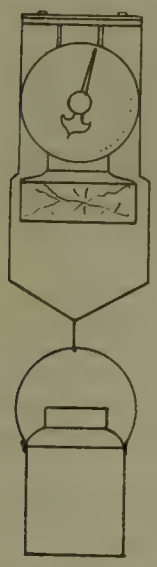


FIG. 1. FRONT VIEW.

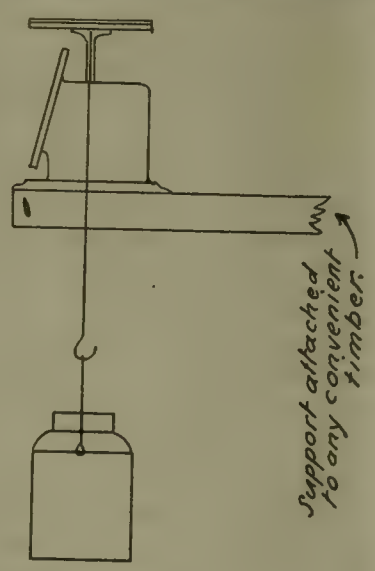

FIG. 2. SIDE VIEW.

disc of heavy detail paper was pasted on the dial, and a sp. gr. scale marked thereon, indicating gravities of Aurora pulp ranging from 1 to 1.75. Calibrating can be done either by interpolation or calculation. The pulp measure used here is an ordinary half-gallon tin milk-can.

The scale is supported on a 2-in. piece, the width of its base, leaving a clear space below the support. The yoke is made of stiff wire twisted together at the bottom to form the hook. The top of the yoke is hinged to a piece of stout galvanized iron, thus leaving it free to swing backward and forward. The iron plate is fitted to the platform of the scale, and held in place by turned-down edges. The reason for suspending the measure below the scale instead of using the platform is to protect the scale from spilled pulp. The interior of this or any other scale of similar type is not immune from pulp dripping down the side of the can, or falling from the dirty hands of the millman, and if the platform were used the accuracy of the scale would soon be impaired. With the measure suspended below, as shown, no moisture or pulp ever comes in contact with the scale.

One scale is set permanently near each place where a number of determinations are made each shift. In this case four sets of apparatus are used. The millman has no occasion to handle the scale, merely confining himself to hooking on the bucket of pulp, taking his reading, and then removing the bucket. The bucket is about the only part of the equipment liable to damage. This style of container will be appreciated by those who have used small-necked bottles or other receptacles. The large mouth of the bucket makes it easy to fill and empty.

This apparatus has the following good features: the scale itself is not expensive, nor are the milk tins; set in a convenient position, it is not handled and put out of adjustment, but will remain reasonably accurate for a long time; determinations are made in a minimum of time and with little trouble; and there are no elusive weights that mysteriously disappear when most urgently wanted.

Dredging Costs at Oroville

Three boats of the Oroville Dredging, Ltd., had the following record during the year ended July 31, 1914:

Actual dredging time, hours per day	20.38
Average gravel handled, cubic yards	3208
Average depth, feet	30.5
	Cents per cubic yard.
Material and labor	1.25
Electric power	0.75
Water	0.08
Repairs	1.06
Smelting and express	0.03
General	0.66
Taxes and insurance	0.21
Total cost	4.04

A total of 2,897,557 cu. yd. yielded $251,599, varying from 7.72 to 12.79c. per yard.

Concentration at Mt. Morgan, Queensland

The new 500-ton mill, as described in the *Press* of December 26, 1914, started in July. According to the report of the Company for the half-year ended November 29, the following results were obtained in the first runs:

	Weight, tons.	Assays: Copper, %	Assays: Gold, dwt.	Recovery: Copper, %	Recovery: Gold, %
Ore treated	31,274	2.365	5.36	....	....
Concentrate produced:					
Table	5,993	3.29	11.44	26.68	40.89
Flotation	3,026	13.94	18.85	57.02	34.00
Total	9,019	6.86	13.93	83.70	74.89

Content of the concentrate was 619 tons copper and 6281 oz. gold.

COAL OUTPUT OF INDIA in 1913 was 15,486,318 tons, an increase of 10.27 per cent.

DISCUSSION

Readers of the Mining Press *are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.*

Amalgamation in Hardinge Mills

The Editor:

Sir—Naturally I take considerable interest in the discussion in the *Press* of January 16 relative to the above subject. The argument, both *pro* and *con*, I must admit is subject to endorsement, owing to the fact that the ores described probably have chemical qualities materially different one from the other. The Mother Lode ores have always been considered very simple to treat. The combined amalgamation and concentration recovery is higher than that of any other district with which I am acquainted. They, however, have a large proportion of a slaty gangue, producing a colloidal slime, which might have a tendency to form a coating on quicksilver which would produce the 'sickening' referred to.

This matter of inside amalgamation was suggested by me to J. M. Elmer, in 1909, when he was in charge of a Mother Lode mine in Tuolumne, California. He then tried it out with highly satisfactory results. Mr. Elmer later reported that the amalgamation recovery advanced from 65 to between 80 and 85%, and a total of over 90% was made with subsequent concentration. From information later gained, however, we must give A. D. Foote, of the North Star mine at Grass Valley, credit for a still earlier use of quicksilver in pebble mills for inside amalgamation. Some months after Mr. Elmer's resignation from the Tuolumne mine, we received a letter from Charles Maass, Mr. Elmer's successor, and from his letter I quote the following:

"The objection usually urged against inside amalgamation, where fine grinding is done, is that the mercury will granulate and thus become useless for amalgamating purposes. This is due to the mercury becoming foul through taking up soluble mineral salts. To prevent this, it is necessary to introduce some agent which will cause the liberation of hydrogen gas from the liquid in the mill, thus deoxidizing the salts when they no longer have an affinity for the mercury. In other words, it is simply necessary to keep the mercury as nearly chemically pure as possible. To accomplish this we have found that, in the case of the silex-lined mill, metallic sodium gives excellent results. In our iron-lined mill the results were not as good, as the action of the metallic sodium was so violent that it caused the amalgam to adhere to such parts of the iron lining as had become brightened through wear. In this case we used an amalgam made up of zinc and aluminum. This also has the effect of liberating hydrogen gas, though the action is slower and will not cause the amalgam to adhere to the polished iron. The objection to the use of this combination lies in the fact that it cannot be made up in quantities to keep, and as a consequence must be made up freshly whenever necessary to add any to the mill.

"To sum up: For successful inside amalgamation in your mills it is only necessary to keep the mercury as nearly chemically pure as possible, and this can be accomplished by the introduction of any agent which will produce nascent hydrogen. As to quantities and proportions, this will vary according to conditions and the nature of the ore treated, and is a matter which can be easily determined by any experienced amalgamator. Mercury should be fed to the mill as freely as possible and yet avoid the resultant amalgam, when it reaches the copper plates from 'running.' It is not our object to catch the amalgam inside the mills, as its recovery there is an expensive matter, but to prepare the amalgam so that it will readily adhere to the copper plates when it leaves the mill.

"Regarding the results we have secured through inside amalgamation in the Hardinge mill, will say that since we have practised this we have cut our concentrate values almost exactly in half, with a corresponding increase in our free gold recovery. Our tailing value has also materially decreased."

From the above, and in view of the internal amalgamation having been carried on successfully for over a year, the results suggest that a failure in one case on the Mother Lode and a success in another, might be due to manipulation rather than physical or chemical conditions of the ores, and also that, as Mr. Elmer suggested in a previous letter, it required some faith to continue the inside amalgamation when he had nothing to show but the difference between heads and tails to recommend its continuance, for it took three or four days before the accumulation of amalgam in the mill produced a normal 'saturation.'

One is likely to jump too hastily at conclusions where gold is concerned. It is this saturation that causes anxiety in the starting up of any new metallurgical plant, from smelting down to chemical extraction. The ores at Tuolumne and those mentioned as at Plymouth both contain a large quantity of slate which forms colloids, which possibly may have some physical effect in coating the 'sickened' quicksilver. It is an open question whether this fouling or sickening is due to the chemical or physical action of an ore.

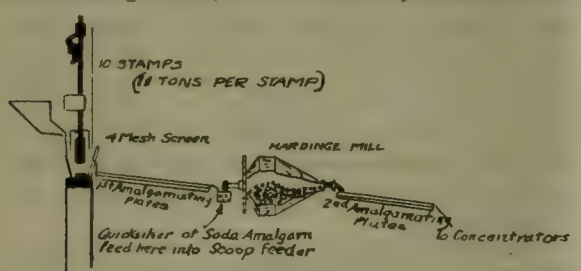
Another instance of jumping at a conclusion in amalgamation in the Hardinge mill came to my attention

in a plant at Jarbidge, Nevada, where excessive losses between heads and tails could not be accounted for. An expert was brought in to check up results, who later reported that all he did was to open the mill, dump the contents, retort three separate balls of 50% amalgam, and hand the manager $16,000 worth of bullion.

Here it was explained that the cause of the trouble was in too small a quantity of quicksilver being added to the charge in proportion to the gold content. As soon as a quantity of quicksilver sufficient to make a fairly liquid gold amalgam was introduced into the mills, the amalgam issued with the charge and was recovered on the plates.

Reverting to the experience at the Incaoro mines, Bolivia, it would appear that this inside ball amalgamation was desirable, not only from a metallurgical result, but also from the fact that 'outside amalgamation on the natives' fingers' was prevented.

The system as practised at Tuolumne is outlined in the following sketch, while at the Plymouth mill the



PLAN OF WORK AT TUOLUMNE.

plate between the stamps and the Hardinge mill was omitted.

From the above I am led to infer that if the quicksilver is fed to the mill with the ore in the form of an amalgam of quicksilver with zinc, silver, sodium, or other metal, there is formed an alloy which is no longer the single element of quicksilver, but a combination or alloy of the elements. Just as brass has a somewhat different physical and chemical action from its components, zinc and copper, so also would amalgam have an effect different from pure quicksilver.

This matter of inside amalgamation in pebble and ball-mills will no doubt be experimented with, but I predict that this will be done with varying results and opinions. A possible loss of a few pounds of quicksilver would, in our opinion, justify the experiment. Flouring or sickening is not due so much to agitation as it is to chemical and physical conditions of the ores under treatment. Experiments on inside amalgamation should be conducted with patience and common sense. The empirical mill investigator, unhampered by theoretical formulae, is more likely to solve this question than the chemist who relies only upon his books in the office.

H. W. HARDINGE.

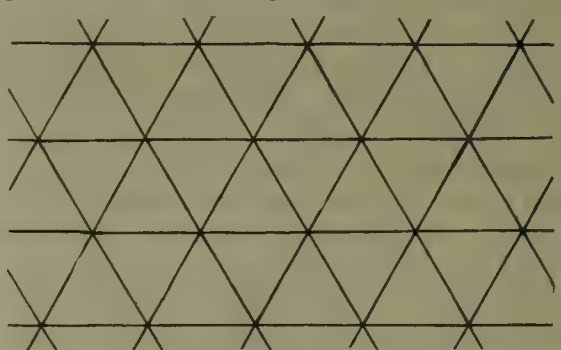
New York, January 28.

Valuation of Dredging Ground

The Editor:

Sir—In the *Press* of September 26, L. J. Hohl's contribution to the discussion on L. A. Decoto's 'Valuation of Dredging Ground' explains the mathematical principles involved in the computation of the average yard value in a clear manner. Although the increasing interest shown in dredging is reflected in the amount of placer boring now being carried on, a surprising lack of uniformity seems to exist in the methods adopted in working out the results. Mr. Hohl has demonstrated what I have always imagined to be the correct way, and also the shortest; and, if this discussion can be the means of inducing everyone to accept one standard form of computation, it will serve a useful purpose.

However, Mr. Hohl says that, as ground can be generally blocked out in a series of squares or triangular half-squares, no other geometrical figures need be considered. I admit that this way of setting out the holes at 90° is the general, if not the invariable practice; but another simple geometrical pattern, easy to lay out in the field, may be adopted by running the lines to intersect at 60°. This gives a series of equilateral triangles, six of which build up a hexagon with a centre point.



Therefore, any hole not on the outside edge of the area is equidistant from the six neighboring holes, and every hole has a balanced effect not to be got on any other pattern. When boring an area of some size and a reasonable width, it does not much matter for practical purposes how the outside holes happen to fit in with the boundaries, and no variation in the lay-out need be made on that account.

The computation of the average yard value should be carried out as explained by Mr. Hohl, each interior hole entering into six triangles. It may be found convenient to set out the bores so that the area of each triangle is an acre, or a simple fraction of one, as follows:

	Feet.
Equilateral triangles of one acre have sides of	317.171
Equilateral triangles of a half acre have sides of	224.274
Equilateral triangles of a quarter acre have sides of	158.586

I shall be interested to learn how this 60° lay-out is regarded by other engineers.

E. J. VALLENTINE.

Intan, Upper Perak, Federated Malay States,
November 27, 1914.

The Mine Mule

The Editor:

Sir—I read with interest in the *Mining Press* of February 6, Mr. Wentworth's comment on the mine mule. As he has obtained his figures as to cost of keep of a mule as compared to the horse, from an agricultural experiment station, and his data are supposed to be authentic, I hesitate to dispute his statement. But I do not hesitate to state that any big teaming outfit, that uses both horses and mules, would say off hand, that a mule, weight for weight, and work for work, will cost considerably less than a horse in keep.

At an experiment station ideal conditions are supposed to obtain for such tests, but the conditions are not ideal. The mule or mules experimented with may have been hearty feeders, and the horses dainty feeders. Why is it that you never can buy a good mule cheaply, whereas at times good horses are practically given away!

I have had considerable practical experience with both horses and mules under varying conditions, and have found that a mule will do a given amount of work, day in and day out, year in and year out, on less feed than a horse. Also a mule will thrive where a horse would starve. Any old prospector will vouch for that statement. The mule will also get along on less water. No one can be a greater admirer of the horse than I am. A horse is a loveable animal and a mule is not; but when it comes to wit, Mr. Wentworth will have to admit that a mule has more wit in a minute than a horse has in a month—to use an exaggerated expression. The mule certainly outshines the horse for wit. We have used mules in the Utica mine for years, and we have found them quick and apt scholars. One never hears of an underground horse; and why? A mule, weight for weight, costs about twice as much as a horse, and still the mule supersedes the horse underground—to which, I suspect, the horse does not object. The mule is used underground because of his superior intelligence, strength, and endurance, and less cost of keep as compared, weight for weight, with the horse. In a low drift a horse would butt his brains out, while Mr. Mule ducks his head and even crouches down when necessary. Maybe a mule is intelligent only as it may affect his well-being, but intelligence remains intelligence, no matter to what use it is put.

Mr. Mule keeps tab on the number of cars you couple on behind him—even when empty—and will let you know that he is 'wise' to you. He also keeps tag on the number of trips to a shift, especially if long hauls. He has strong union proclivities, and objects to doing a hand's turn, or foot's turn, when the regular work has been performed.

Maybe it is his 'tummy' that keeps time, for he seems to know when it's quitting time. Where it is necessary to dump a train of cars, separately at a given point, he will know after a trip or two just when and where to start and stop. There is an old expression extant, 'cute as a mule,' which does not belie him.

His bad point is his contrariness. When I was stationed in Arizona, I used to make occasional trips out on the desert, where it would be necessary to haul drinking water along, and not wishing to be overloaded, would take just enough to last until the next water was reached. Naturally, it had to be carefully husbanded. I always planned to have the mules take a good big drink before leaving; but never a drink would they take. But, offer them a drink ten minutes after leaving on the trip, from the supply being carried along, when too late to replenish it, and the brutes would drink the whole supply if offered. Now this does not argue intelligence; but I believe it was pure contrariness. It may be that the mules considered that the water would be easier and safer to carry inside than to haul. We all have our limits in intelligence, and so has the mule.

F. J. Martin.

Angels Camp, California, February 7.

[We are glad to have someone speak up for the mule when criticized. While he is abundantly able to kick for himself, he must rely on his friends, the miners, when it comes to writing for the papers. Just why mules have been preferred in coal mines and horses in metal mines is a mystery we have never solved. Does anyone know? —Editor.]

Smelting Copper Sulphide Ores

The Editor:

Sir—I have had considerable discussion lately concerning the smelting of sulphide ore, with prominent smelting men, some of whom claim that great improvements have been made in blast-furnace smelting during the past few years. I fail to see where these improvements are; the only thing that I will admit is that the furnaces have been increased in size, but this increase has been going on for over 30 years. During the first 15 years, furnaces increased from 3 to 20 ft. in length, and then from 20 to 50 ft. in length. There has not been what might be termed any metallurgical improvement, such as the utilization as fuel of more of the sulphur content of the ore, or reduction in the quantity of coke used, which would mean a reduction in the quantity of ore roasted and an all around saving in the cost of smelting. The fact is that with excessively high-blast pressure, more coke is used and less sulphur oxidized and a lower-grade matte is produced. I maintain that smeltermen are using more coke and producing a lower grade matte today in the large furnaces than they were 20 years ago, when smelting in furnaces with a capacity of 150 tons per day.

Take, for instance, the large smelters in Arizona at the present time, using 15% coke and producing a low-grade matte. During the time the smelters had a capacity of 150 tons per day in several of the smelting plants the consumption of coke did not exceed 11%. What is the cause of this great difference? Why should 15% coke be used to smelt sulphide ore when from 5 to 10% will do the work with less blast and produce a

higher grade matte and also increase the smelting capacity of the furnace?

At the Copper Belle mine, Gleeson, Arizona, in the year 1904, I smelted copper sulphide ore with 7½% coke (coke containing 24% ash) in an old blast-furnace 36 by 76 in. The furnace ran on sulphide ore containing 38% sulphur and 4% copper, two parts; and sulphide ore containing 16% sulphur and 5% copper, one part, with some silicious silver ore, producing a matte containing 26 to 30% copper and 22 to 28 oz. silver per ton. The following figures were copied from old charge sheets of the Copper Belle smelter:

	Tons.
Sulphide ore (38% sulphur)	2883.00
Sulphide ore (16% sulphur)	1446.00
Silver-bearing quartz	316.10
Foul slag	267.00
Matte re-smelted (24% sulphur)	102.00
Coke	378.20

The amount of charge smelted was 5014.10 tons with 378.20 tons of coke, or 7.54% coke on the charge, the sulphur content of the charge averaging 26.94%. The furnace was run during the day shift only, the blast being put on at 6 a.m. and shut off at 6 p.m. At night the furnace was left full of charge right up to the charging door, and about 30 minutes after the blast was put on in the morning the slag was running freely from the furnace. There was no trouble with the furnace freezing up. If the furnace had been run night and day shift continuously we could have smelted with 6% coke. I do not consider this as being exceptionally good work, but there is no smelter in Arizona doing even approximately as good smelting at this time even with their modern plants. In the year 1888 I went to Venezuela for the Quebrada Railway Land & Copper Co. and found that they were using mahogany wood to roast sulphide ore containing 40% sulphur, and using coke (made from coal, 45% of which was consumed in producing this coke) to smelt the roasted ore. This struck me as a very extravagant and idiotic method of treating ore, first to use fuel (wood) to burn fuel (sulphur) out of the ore which should be utilized. Second, burning 45% of the fuel value of coal to make coke to smelt the ore already deprived of more than sufficient fuel to smelt itself. But smeltermen are doing no better today. Large roasting plants are built, using coal or oil to roast the sulphur out of the ore, and coke is made by burning 45% of the coal or fuel value, and then used to smelt the sulphide ore already deprived of its natural fuel. So I cannot see where any progress has been made in blast-furnace smelting of sulphide ore. Smelters are simply using a furnace with a method which was designed to smelt oxide ore and which has a reducing action, while in smelting sulphide ore an oxidizing action is required, which is directly opposite to what is being done. There is plenty of room here for improvement, but do the copper smelting companies want to improve their methods? I think not.

WILLIAM KEMP.

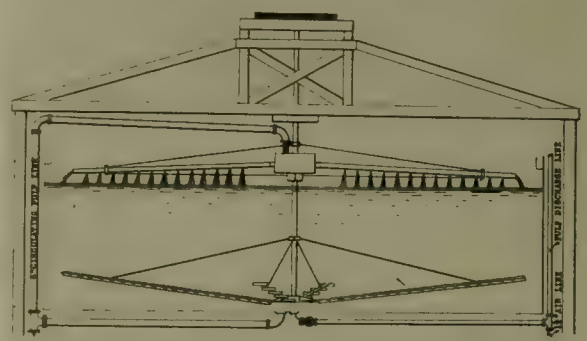
Tucson, Arizona, January 9.

An Agitator From a Thickener

The Editor:

Sir—The remodeling of a Dorr thickener into an agitator at the Commonwealth mill at Pearce, Arizona, is interesting because of the simplicity of the change, and the increased agitation capacity gained at slight cost. The thickener was one of two 38 by 12-ft. placed after the classifiers of the sliming department, and delivering thickened pulp to a line of nine 38 by 12-ft. Pachucas. They were designed to handle half of the mill flow each, but tests showed that one thickener was sufficient.

The purpose of the change was to prolong the period of agitation, and was effected by changing the speed of the arms from one revolution in five minutes to two revolutions in one minute, adding an air-lift for circulating the pulp from the bottom to the top of the tank,



and a radial launder for its distribution. The original shafting, arms, and drive gear was used.

The Dorr agitator and its companion thickener are driven from a common line shaft by a 3-hp. motor, the overload alarms on the two showing the same load.

The air for the 6-in. circulating pulp air-lift is supplied by a 1¼-in. pipe, the valve being 'cracked' only. The air pressure is the same as that supplied for the Pachuca agitators, that is, 20 lb., a higher pressure than that needed for economical work. Whitman Symmes gives figures for air consumption at varying pressures, lift being constant and ratio of liquid to solid of 2 to 1, as follows: air pressures of 8, 10, and 15 lb. require 29, 80, and 94 cu. ft. per minute, respectively, so that for the lift necessary for the pulp circulation, 10 lb. would be ample. The total power consumed certainly does not exceed 3½ hp., and as the capacity of the tank when filled to 10 ft. with a 2-to-1 pulp is 118 tons dry weight, the cost per ton agitated is low. The pulp handled is a quartzose slime, 1.25 to 1.30 sp. gr., 70% passing 200 mesh.

Since the agitator has been in use there has been trouble from the 'sanding up' of the Pachuca agitators to which it delivers pulp, although the passage of that pulp through the Dorr agitator gave no trouble.

The agitator was stopped on one occasion for 2½ hours, yet started without raising the arms.

D. W. MINIER.

Pearce, Arizona, January 15.

CONCENTRATES

Readers of the MINING PRESS *are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.*

MEN EMPLOYED in metal mines, coal mines, and quarries of the United States totaled 1,047,010 in 1913. There were 3651 fatalities, equal to 3.49 per 1000 employed.

THE REMEDY, or variation allowed in England on the fineness of bullion above or below that legally standardized, amounts to 2 parts per 1000 for gold bullion and 4 parts per 1000 for silver bullion.

POPULATION of the Canal zone and the towns of Panama and Colon, based on a census taken between December 22, 1914, and January 1, 1915, shows about 120,000 persons resident therein. The zone has 31,160 at present.

GOLD, SILVER, COPPER, LEAD, AND ZINC production *per capita* of population of the western states is as follows: Alaska, $298.38; Arizona, $346.76; California, $11.55; Colorado, $44.35; Montana, $164.65; Nevada, $459.21; South Dakota, $12.71; and Utah, $122.02. This is based on the census of 1910 and production in 1913.

COINS are to be made at the Panama-Pacific Exposition at San Francisco. Authority has been granted to the Mint to execute 3000 of $50, 10,000 of $2.50, and 25,000 of $1 gold pieces; and 200,000 of 50-cent silver. These will all be of the legal weight and fineness. Half of the $50 coins will be octagonal, similar to those issued in 1851.

BOILERS EXAMINED internally and externally in Montana in 1914 by the inspector, P. L. Brown, totaled 4301. There were 5695 defects noted, 2917 of which were considered dangerous, and suitable repairs were ordered made. Thirty-one boilers were condemned as unfit for further use, and the pressure was reduced on 1450 others.

NATIONAL FOREST AREAS of the United States were threatened with 6112 fires in 1914, up to December 1, with probable outbreaks in southern California and certain parts of the East. Of this total, 81% was extinguished by the Forest Service of the U. S. Department of Agriculture before 10 acres had been burned. The loss of merchantable timber in 1914 was about $400,000, against about $15,000,000 in 1910. In Montana and Idaho, 2000 fires threatened timber worth over $59,000,000, but were put out in time; and in Washington and Oregon fires menaced a property value of $24,000,000.

MOISTURE IN TUBE-MILL FEED should be approximately 38% by weight, if maximum efficiency for power consumption is desired. In some installations, however, where the regrinding plant is overloaded under these conditions, it is practicable to reduce the percentage of moisture below this limit, the increased power consumption being counterbalanced by increased economy in other parts of the plant following the handling of a larger tonnage.

COSTS at the Ashanti Goldfields property, West Africa, totaled $11.61 per ton during the past financial year. This included mine development, shaft sinking, London expenses, royalty, and prospecting, but not construction and treatment of old tailing. This cost is expected to increase somewhat on account of mining the Obuasi ore-shoot. Mining cost $1.74; retimbering, 22c.; ore transport, 12c.; treatment, $4.48; and general charges, $1.32 per ton. The miscellaneous expenses are high, amounting to $58,000, or 5c. per ton, but this includes sanitation, medical, holiday, and royalty pay, and white staff transit, rendered necessary in that climate.

ORE from the Cam & Motor mine, Rhodesia, contains antimony, as has been mentioned in this journal before, and the recovery in the new mill is now only 73%. A great deal of experimenting has been done, and the following will be the flow-sheet: The roasted ore will be first pulped with water in order to wash out the deleterious compounds before mixing with cyanide solution. Coarse sand will be separated for tube-milling by Deister classifiers. The ground product will then be classified into sand and slime by Dorr classifiers, and, as the gold content in the sand is quickly dissolved, it is proposed to treat this product in small tanks with cyanide solution. Finally the sand will undergo a short leaching treatment in vats. The slime treatment will consist of continuous decantation on the Dorr system.

PROSPECTORS' METHODS are useful for others than miners at times. During the making of some indicator cards in the engine-room at one of the Coffeyville factories, Kansas, the engineer accidentally dropped one of the very small brass screws for the indicator down into the flywheel pit. The bottom of the pit was partly covered with dirt, sweepings, etc., which promised to make the recovery of the screw all but impossible. One of the helpers about the place had once been a prospector, and said that he could recover the screw immediately. This is how he did it, according to J. I. Blair: Taking the engineer's wash-basin, he dropped into the pit, and carefully skimmed the surface of the slime and mud. Then going to a tank of water he panned the dirt, with the result that the screw was quickly found, and the cards finished.

MINING IN THE FAR NORTH

Ruby District: Prospecting, Gravel Washing, and Gold Production

By EMIL EDWARD HURJA

Perhaps more life was evident in the Ruby district during the season of 1914 than in any other interior camp visited. The revival from the depression which followed the stampede of 1911 and 1912 was due to the discovery of good 'pay' in quantity on the benches of creeks originally prospected and deemed worthless, as well as the finding of gold on streams of the adjacent Innoko watershed. The 1914 production has been estimated variously at $750,000 and $1,000,000. The 1912 production was $300,000; that of 1913 amounted to $550,000.

The first attention to placer prospecting was given the Ruby district in 1907, when prospectors found colors in Ruby creek,

RUBY TOWNSITE, MAY 1911, AND MAIN STREET, AUGUST 1914.

a three-mile stream emptying into the Yukon from the south near the present site of the town of Ruby. Many mining men stampeded there from the Fairbanks and Hot Springs districts, but the resultant prospecting did not yield any appreciable results.

In 1911, Fornander and Johnson, two prospectors, found gold in profitable quantities on Long creek, at the mouth of Bear creek. They staked the discovery claim, and carried on prospecting for some months before allowing news of the find to seep out into the Alaskan camps. By June of that year, however, the stampede was in full swing, and Ruby grew in a few months from a few tents to a healthy town. The population was estimated at from 1000 to 1500 for the summer of 1911 and 1912. Many of the surrounding creeks were staked, and as the old association claim law was still in force, the claims were all 160 acres in extent. Because the old law demanded but $100 worth of work on each association, no real development ever resulted, and the next year or two after the first discovery marked no advance in the future of the district.

When the Wickersham law went into force, limiting the number and size of the locations, the revival in prospecting started. That the operation of the law has been a godsend to the Ruby district is the opinion of the mining men of the camp. It has made the recent development possible, as prospectors are encouraged to develop their claims, particularly because one of the provisions of the act is that $100 worth of assessment work must be done annually on each 20 acres of placer ground. The Ruby district embraces, roughly speaking, 1000 square miles of territory, lying about 175 miles below Tanana, and 110 miles above Nulato, on the southern bank of the Yukon.

Most of the mining is done in the Salatna watershed, the headwater tributaries furnishing most of the gold. The Innoko streams on the other side of the divide also have been showing gold in profitable quantities. The mining district is situated south of Ruby City, 30 miles by the direct winter trail or 42 miles by the long summer road along the summits of intervening ridges. The United States government, through the War Department, has expended considerable money in road building in the district, but not enough to make hauling conditions satisfactory to the mining men of the district.

The work on Long creek and its tributary, Bear Pup, will be the first to be considered. Burke & Strite, operating on 3, Bear Pup, have been employing 40 men in two shifts all summer long on their lay. The ground is 16 ft. deep, of which from 6 to 8 ft. is pay-gravel. The overburden of 'muck' and waste gravel is ground-sluiced off, and the gravel scraped into the sluice-boxes by slip scrapers operated by steam. The season's product of the claim was 50,000 sq. ft. of bedrock. John Gidlund & Co., formerly of the Dome Creek district in Fairbanks, own and operate No. 1 and No. 2 Below, Bear Pup. They employed 50 men during a greater part of the summer, and mined 55,000 sq. ft. of bedrock.

X. Ditz & Co., operating ground owned by B. H. Walker and M. Sells, are reported to have opened 'pay' this summer which averaged over $6 to the square foot. The work is conducted on the Mascot bench, opposite No. 1, Bear Pup, on the left limit. The pay-streak is in the bench gravel, at a depth of 65 ft. Another 40-ft. streak was found 200 ft. away. Forty men were employed this summer, in two shifts, with a 50-hp. boiler capacity for the plant. As the ground is wet, pumping has been necessary.

Below Ditz & Co., on the Windy bench claim, the A. L. Kells company had a crew of 20 men working during the summer in ground 65 ft. deep that averaged $2 to the square foot. Below the Windy bench, Erickson & Graham worked during the summer on the Deacon bench. They had a 20-hp. plant and employed 10 men. Webber & Co. worked the lower end of Deacon creek, with a 20-hp. plant and a small crew of men. Buckley Brothers are blocking out on the Novikaket claim, situated at the mouth of Fourth of July creek, a Long tributary. They have a 30-hp. plant on the ground and intend to do considerable work during the winter, when the ground is solid and permits easy hoisting. Wally LaBoski has a 20-hp. plant and five or six men at work at the mouth of Fourth of July creek. E. W. Ward & Co. have a small plant on the Keystone claim, with a 20-hp. boiler and five shovelers. Farther down in the Long Creek valley, Ives & Larson worked a small open-cut this summer on Short creek, a tributary to

Long on the left limit. On upper Long creek Alex Larson had a 30-hp. plant at work all summer on 2 Above Discovery claim. Twenty-five men were kept at work and considerable pay was hoisted.

Perhaps the most important development of the season in the Ruby district is the planning for a dredge on Greenstone creek, where was announced late in the summer following an examination of ground by Walter Johnson of the Union Construction Co. Greenstone creek is a tributary of Long creek emptying into it on the left limit about seven miles below Discovery claim. John Holmgren, Peter Jensen, and several others have worked an open cut on Greenstone during the past two summers. The creek is five miles long, and three miles has been secured for dredging purposes by the Company. This has been thoroughly prospected, and some 300,000 sq. ft. of bedrock was scraped into the boxes this summer. The dredge will have buckets of 1-cu. ft. capacity. It will be constructed by the Union Construction Co. of San Francisco, to be shipped by water to Ruby and freighted from there to the creeks during the winter of 1915-16.

On Midnight creek, also tributary to Long, a lot of prospecting is being done. Some fair ground was worked there two winters ago. On Swift creek, tributary to Basin, John Hanson, prospecting on the right limit, recently found 'pay' averaging $1.50 per square foot. The ground is 16 ft. deep. Hanlon & Co. are working on Monument creek, a tributary of the Salatna river from the north. Five feet of pay-gravel has been found, but water invaded the workings recently and they have not done anything for a few months. They expect to resume work as soon as cold weather furnishes an opportunity to free the workings from water. Tamarack creek, a Salatna tributary from the south, has several prospecting plants on it. One is owned by McGillis & Co. They are reported to have found ground averaging $2 per square foot, but had not definitely ascertained the width of the pay-streak.

One of the most recent indications of the healthy tone of mining in the Ruby district was evident in the organization of the Ruby Development Co. by business and professional men of the camp. The Company obtained a Keystone drill from Nome late in the fall, and expected to start work immediately. The holdings of the Company will be tested, and then it is planned to drill ground for others for an interest. Several quartz lodes have been staked in the Ruby district, but assays made of what was considered the more promising one showed only a very faint trace of gold.

RUBY, ALASKA, IN JUNE 1912.

THE CARRIER DUMPING INTO SLUICE-BOXES, LONG CREEK, RUBY.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

NEW YORK

COPPER AND ZINC.—UNITED STATES SMELTING, REFINING & MINING CO. INCREASES OPERATIONS IN MEXICO.

Resumption by the Calumet & Hecla of normal production results in practically all the Lake Superior mines being at capacity, and foreshadows what the most of the other copper companies in the United States will probably be doing before long. The Anaconda made a small increase in its January output, and a similar tendency will likely be reflected in the January figures for the other companies when these are available. Copper has risen to about its normal level, and if it were to go much above, with the companies operating at only part capacity, there would be not a little probability that some of the consumers would begin to talk about conspiracies in restraint of trade. Of course, it is much to the advantage of all the companies to work at full capacity if the consumption will permit, and it is quite evident that that time has not yet arrived, as exports for the past four months have been about two-thirds of the average for 1913. Domestic consumption probably has been similarly restricted. The Department of Commerce has just given out figures showing that in 1914 copper exports amounted to 840,080,922 lb., compared with 926,241,092 lb. in 1913. As the exports in the first half of 1914 were higher than the average of 1913, the net decrease of 86,000,000 lb. for the year represents the very large falling off in exports since the war broke out.

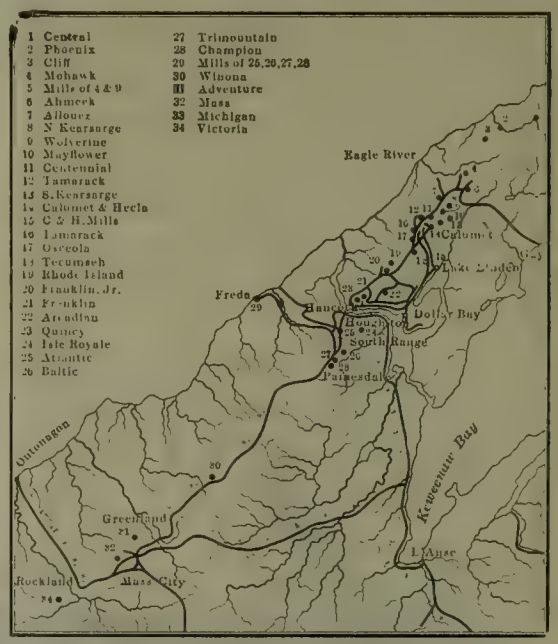
The high price to which spelter has risen has given rise to an amusing canard which circulated in New York last week. This alleged that the reason for the high price of zinc was that the metal is controlled in this country by sellers of German extraction, and that they had boosted the price of the metal to its present high figure in order to hamper the British as much as possible. Apparently those who started the story were quite unaware that the smelters about which the armies are now fighting produced nearly half of the world's output of zinc in 1913, and that the Butte & Superior, the largest single producer in America, has been shut down for several months on account of repairs to its shaft. The lead producers will doubtless be interested to learn the secret of boosting the price of a metal when desired, as that metal is characteristically dull. There is a real shortage of the highest grade of spelter, since a great deal of the present buying is for the manufacture of cartridge cases, for which the New Jersey Zinc Co.'s 'Horsehead' brand enjoys the highest reputation. Apparently there is not enough of this available to meet the demand, for it has sold as high as 15c. per pound and there is a strong market for other high grades of spelter. Now that the Butte & Superior is operating again, it is probable that the price of the metal will ease off, as that Company can produce about 5000 tons of spelter per month, or one-sixth of the total United States output.

Reports from Mexico state that the United States Smelting, Refining & Mining Co. has been able to increase considerably the output of its mines at Real del Monte and Pachuca since the first of January. For a while the properties were so hampered by the revolution that they were running at only about one-third capacity, but conditions have now been improved until the mines are making about two-thirds of their normal output. When the question of cyanide supplies from Germany was in doubt, the situation looked very dubious, but since then a sufficient supply has been received from that country, and there is now no trouble on that score. The decline in the price of silver is, of course, a serious matter for this Company, since nearly half of its gross output is derived from its silver mines. The Company's Utah coal mines are reported to have produced only 800,000 tons in 1914. This is a disappointment, since it requires a production of about 1,000,000 tons to produce net earnings sufficient to take care of the interest on the bond issue outstanding. It had been hoped that the increase in production last year would be sufficient to take care of this, but as a result of the bad conditions in general business the hoped-for increase did not materialize.

HOUGHTON, MICHIGAN

NORMAL CONDITIONS RETURNING.—TONNAGE TAX.—STAMP-MILL NOTES.—ISLE ROYALE SHAFT.

The Copper Country is gradually returning to a more normal condition. Feeling keenly the effects of the Western Federation strike and the curtailment due to the European war, Michigan operators are willing to take advantage of every opportunity the copper market may offer. The Calumet



MAP OF THE COPPER COUNTRY, MICHIGAN.

& Hecla and all its subsidiaries will run full time from now on. This new schedule will mean an average of 26 working days per month instead of 20. The old Osceola branch of the Osceola Consolidated and the Centennial mines have been operating full time for over two months. This will probably not mean any increase in the forces now working.

People of the Michigan copper and iron districts have been much concerned over the proposed tonnage tax. A report comes from Lansing that at the recent meeting of the execu-

tive committee of the state grange it was decided not to ask for a tonnage tax bill during the present session of the legislature.

It is reported that repairs are now being made to the old Tamarack stamp-mill preparatory to placing in commission two heads for the treatment of rock from the Isle Royale mine, which mill was recently destroyed by fire. The Tamarack mill was closed when the strike was called in July 1913. The Centennial-Allouez mill is now handling rock from the Isle Royale and Superior mines and is working at full capacity. Because of the present large tonnage of these two mines, it was necessary to transfer the small output of the Winona mine to the Trimountain mill of the Copper Range Consolidated. The Winona rock is now stamped at higher cost than at the Centennial-Allouez mill, but the shorter haulage just about makes up for the difference. The stamp-mill of the Mohawk and Wolverine mines is also being worked overtime to handle the large tonnage from these two mines.

The report comes from Boston that the directors of the Isle Royale have decided to proceed with the repairing of the No. 1 shaft, which was destroyed by fire several years ago. It is reported that the repairs will cost from $2500 to $3000 per month, and will require from six to eight months' work. The repair work on this old shaft was undertaken last summer, but the work was suspended in the fall, when all construction work ceased.

WASHINGTON, D. C.

CHANCES SEEM GOOD FOR PASSING THE BILL FOR MINE EXPERIMENT AND SAFETY STATIONS.—GERMAN POTASH.

At least one mining bill has now a chance to go through Congress at this short session, provided the shipping legislation is finished in time before March 4. This bill is that of Congressman Foster, from Illinois, and chairman of the House Committee on Mines and Mining, providing for mining experiment and mine-safety stations. Some opposition was expected to the bill on account of the large appropriations involved in the measure, about $750,000, but as read to the House no figures were specified as to the sum required, and so no obstruction was encountered on that score. The bill simply authorizes the creation of the stations, and it remains for future committees on appropriations actually to supply the money required, but there ought to be no trouble over that, for the provisions of Congress are mandatory enough. The bill came up in the House under suspension of the rules, and required a two-thirds vote to pass it. No opposition was encountered, and so it passed practically by unanimous consent. Nor was there much questioning. It is expected that 2,000,000 miners will be benefited by the bill. It is so short and reads so well that it carries its own description admirably, being as follows:

"*Be it enacted, etc.*, That the Secretary of the Interior is hereby authorized and directed to establish and maintain in the several important mining regions of the United States and the Territory of Alaska, as Congress may appropriate for the necessary employees and other expenses, under the Bureau of Mines and in accordance with the provisions of the act establishing said bureau, 10 mining experiment stations and 15 mine safety stations, movable or stationary, including those already established, the province and duty of which shall be to make investigations and disseminate information with a view to improving conditions in the mining, quarrying, metallurgical, and other mineral industries, safeguarding life among employees, preventing unnecessary waste of resources, and otherwise contributing to the advancement of these industries: *Provided*, That not more than three mining experiment stations and mine safety stations hereinabove authorized shall be established in any one fiscal year under the appropriations made therefor. * * * That the Secretary of the Interior is hereby authorized to accept lands, buildings or other contributions from the several states offering to cooperate in carrying out the purposes of this act."

The senators interested want to pass the bill in the Senate with all expedition, and Senator Shafroth of Colorado has asked that a special meeting of the mining committee of the Senate be called to hasten the measure, passed by the House, in the Senate. As it is, the bill is in good parliamentary position, as it, in like words, practically has already been favorably reported out of the committee, and put on the calendar of the Senate, and awaits only consideration there, when that body can consider bills other than the ship-purchase bill and the appropriation bills. If the jam is ever broken in the Senate, legislation unobjected to, as is this mining bill, will move with remarkable celerity. All that will really have to be done is to move the substitution of the House bill for the Senate bill, and this the mines committee will be able to arrange.

Miners of potash salts will be interested to learn that the State Department has official information from Germany that the Kali Syndicate, on February 1, in Berlin, decided to form a commission for the denaturing of potash salts so as to preclude the possibility of using them for ammunition and military purposes, and making them valuable only for fertilizers. Upon the report of the commission, the Syndicate will confer with the government relative to moderating the embargo on potash. It is declared that the Syndicate would be seriously embarrassed by a continued absolute embargo, and that large quantities of salts now under way would be detained.

LONDON

INSTITUTION OF MINING AND METALLURGY AND INSTITUTION OF MINING ENGINEERS RECEIVE ROYAL CHARTERS: THIS HONOR EXPLAINED; OTHER SOCIETIES.

The granting of royal charters to the Institution of Mining and Metallurgy and to the Institution of Mining Engineers is an event of importance to the mining profession in Great Britain, though naturally in America the advantages will not appear particularly obvious. Let it be said at once that the royal prerogative of giving the charters is not quite the same thing as the prerogative of bestowing the garter on the Earl of Chesterfield, who was at one time chairman of Stratton's Independence. The election of the noble earl to the knighthood of the garter at New Years was not in recognition of his services to mining, but as a pleasant personal recognition of his life-long connection with the court. The granting of a charter to a society is something very different. An application for a charter goes before the authorities of the Privy Council, who carefully sift the evidence as to the reputation of the members and council of such society, ascertain whether the objects and the methods of propagating them are of public benefit and interest, and judge whether the society as a body can rightfully claim a share in the advancement of knowledge and its beneficent application. The men who sit in judgment are not politicians or time-servers, so that lobbying is of no help. Nor are the aims the only point considered. The society has also to prove that it has 'made good.' Thus the granting of a charter is a public recognition of the standing of a society. It becomes an 'institution,' not a 'club' nor 'debating society.' Not only has the society to convince the Privy Council of its suitability to receive the honor, but it has to run the gauntlet of criticism and stern opposition of older societies that already belong to the privileged circle. For instance, when a society interested in any branch of engineering applies for a charter, it becomes exposed to violent counter attacks (as the military dispatches say) from the Institution of Civil Engineers. This, being the doyen of engineering societies, considers that it covers the whole range of subjects effectively, but the papers of interest to the mining

engineer read at the meetings during the past 30 years may be counted on the fingers of one hand without reckoning the thumb. It is true that a small proportion of our friends connected with metalliferous mining are members or associate members of the 'Civils,' but nearly all joined before the formation of the Institution of Mining and Metallurgy, or in its earlier days before it had got properly on its feet. The Civil Institution has been making itself ridiculous lately by attempting to dragoon its members in all sorts of pettifogging ways. Not only must you not carry a professional card in a reputable technical paper but you must not answer an advertisement offering an appointment. In the last circular relating to technical education issued by the 'Civils,' the word 'mining' is not once mentioned. How can they say that they take a human or practical interest in the welfare of a great industry and of the men who earn their living in it and who have its prosperity at heart? However, their day is ended as far as the professional control of mining is concerned, and in all probability a number of our mining friends will withdraw from membership, now that the two mining institutions have won their charters.

In all probability the American reader will wonder why there are two societies in England connected with mining, worthy of receiving a royal charter. The explanation is that the iron and coal interests in Great Britain are entirely separate from those connected with the non-ferrous metals. Gold, silver, lead, copper, and zinc are not produced in this country to any great extent but the number of English engineers connected with the mining of these metals abroad is large. The only metal of importance other than iron produced in this country is tin, and the tin miners are so much identified with ventures in other parts of the world, that their affiliation with a cosmopolitan society is more natural than one with the society devoted to the home industries of coal and iron. Thus the Institution of Mining and Metallurgy claims as its objects the advancement of the science and practice of mining in respect of minerals other than coal, and metallurgy in respect of metals other than iron. The Institution of Mining Engineers fills the rest of the bill. It is interesting to glance through the history of the two societies. The Institution of Mining and Metallurgy was founded in London in 1891, and last year its prosperity was so great as to warrant the purchase of a freehold house in Finsbury Circus. The Institution of Mining Engineers has had an entirely different history, as it was formed in 1889 as a federation of seven local societies, the name and dates of foundation of which I give as follows: The Manchester Geological and Mining Society, 1838; the North of England Institute of Mining and Mechanical Engineers, 1852; the Midland Institute of Mining, Civil, and Mechanical Engineers, 1857; the South Staffordshire and Warwickshire Institute of Mining Engineers, 1867; the Midland Counties Institution of Engineers, 1871; the North Staffordshire Institute of Mining and Mechanical Engineers, 1872; and the Mining Institute of Scotland, 1878. Of these societies, the North of England Institute was always the most powerful, and in fact organized the formation of the federated society. It is noteworthy that for some reason the South Wales Institute of Engineers never joined the federation, presumably being desirous of retaining its cherished nationality.

The second general meeting of the Institution of Mining and Metallurgy was held in London on December 17, 1914, F. H. Hatch, the president, being in the chair. After business was concluded, members took up the adjourned discussion on 'Persistence of Ore in Depth,' by T. A. Rickard. Those taking part were H. F. Marriott, S. J. Truscott, J. Morrow Campbell, J. W. Evans, and the author. The latter said that his paper might have been called 'The Impoverishment of Ore in Depth,' or 'The Continuity of Mining in Depth.' Contributed remarks were given by C. Baring Horwood, S. J. Speak, A. R. Weigall, H. F. Collins, J. H. Collins, E. Homersham, Henry Louis, J. H. Goodchild, and George E. Collins.

PLATTEVILLE, WISCONSIN

Extraordinary Features of the Spelter Market in January, and Results.—Bad Weather Affects Operations.—Lead and Carbonate Transactions.—District Production and Buyers.

The month of January 1915 will pass into the history of the zinc-mining industry as one of the most exciting ever recorded. The beginning of the month showed spelter in good form, East St. Louis ranging from $5.50 to $5.75 per 100 lb. The third week showed mysterious undercurrents at work, giving apprehensive minds something to ponder over. The U. S. Geological Survey, usually prompt in distributing spelter statistics, notified correspondents that producers refused to divulge vital data regarding production. Later, discriminating people associated this attitude on the part of the smelters as a keen move on their part to keep mining concerns in the dark and in this manner hold down the price of blende ore. In this the spelter manufacturers succeeded admirably for a time, but when the secret finally leaked out they brought down on their heads the wrath of the ore producers, who are primed for measures of retaliation not soon

FIRST STAGES IN WISCONSIN MINING.

to be discarded. The local correspondent of the *Mining Press*, puzzled at the wide divergence between current newspaper and trade journal quotations and prices admitted by large consumers of metal, interviewed one of the leading officials of one of the largest spelter manufacturing concerns in this country, who readily admitted that large tonnages had been disposed of at from 25 to 30 points in advance of published quotations. It was even then stated that producers were seriously considering the advisability of withdrawing quotations entirely, as they were sold out for February and March. The last week of the month witnessed metal quotations breaking all restraints, and the close of the month carried St. Louis quotations at $7.25, with sheet-metal quotations withdrawn entirely after having rounded the 10c. mark.

The immediate causes of this sky-rocket ascension is found in first an avalanche of foreign buying orders, and the disposition of home consumers laying low on buying orders, with restricted inventories, in the belief that the metal market was being manipulated. When they finally awakened to the real situation there was a scramble to cover buying orders, and bids were made freely at $6.50 to $6.75, but without avail. Many large consumers found themselves 'in bad,' and their importunities for metal are apt to set spelter at prohibitive figures.

The blende markets were somewhat slow to respond to the quickened tone in the spelter markets, but when the true situation was revealed, there came incidents identical with the flurry witnessed in the metal exchanges. December had

closed at $52 per ton for standard commercial ore, and this figure was well maintained until about the 20th of the month when the ore began to climb, and the close of the month found buyers anxious to close on a base of $60, with premiums commanding prices in advance of this exceptional figure. Production was low even at these prices, owing to severe winter weather. Gasoline and electric driven plants without heating arrangements were in many cases compelled to shut down temporarily, and even steam heated plants found it difficult to keep plumbing and milling machinery keyed up efficiently in the face of 10 to 20° below zero weather. Heavy snowstorms drifted the roads badly, and all outlying producers were as completely shut off from transportation facilities as if located in the Arctic zone. Prospect and mine development work, which had received fresh impetus under the glowing advances in the price of metal and ore, were retarded seriously by the weather. Yet, in the face of these difficulties, the field made a fair showing in output and deliveries for the month.

Lead ore was in poor demand all the month, and prices remained stagnant, $47 per ton being the best offer made on a basis of 80% metal. Pyrite producers received little encouragement, and production reached the lowest level recorded in years. Some ore is being carried over, less than 1000 tons all told.

Miners of carbonate zinc ore in the northern districts of the field were sadly mistreated. Prices bounded up toward the close of the month to a point never reached before in all the history of mining in this class of ore, $27 to $32 being the range on a basis of 40% metal content, but buyers refused to pay any attention to producers, and absolutely no ore cleared for the entire month. Production was good, an even score of operating concerns digging with increased forces. The 1914 output is being carried over intact, and thousands of dollars are tied up in the ore-piles, mostly represented through the single item of labor alone. However, miners are far from despondent. They claim their day is coming, and that good profits will be realized on their investment. Over 1500 tons of this grade of ore was carried over at the close of the year.

The following ore deliveries were reported for the month of January, by districts:

District.	Zinc, pounds.	Lead, pounds.	Pyrite, pounds.
Benton	8,584,000	220,000	1,950,000
Galena	5,424,000	.....	.....
Hazel Green	3,662,000	.....	.....
Livingston	3,560,000	.....	.....
Cuba	3,024,000	.....	.....
Platteville	1,948,000	.....	.....
Linden	1,678,000	.....	.....
Mifflin	1,612,000	.....	.....
Highland	460,000	.....	.....
Rewey	126,000	.....	.....
Shullsburg	120,000	.....	.....
Mineral Point	72,000	.....	.....
Total	30,270,000	220,000	1,950,000

The Mineral Point Zinc Co. delivered 61 cars (4,652,000 lb.) of high-grade ore to DePue during the month. The gross production of raw ore from all mines totaled 26,011,960 lb., and net deliveries to smelter 21,083,380 pounds.

Sales were distributed among buying concerns as follows: Mineral Point Zinc Co., 6679 tons; National Separating Works, 2373 tons; Grasselli Chemical Co., 1541 tons; M. & H. Zinc Co., 990 tons; Illinois Zinc Co., 947 tons; American Metals Co., 585 tons; Linden Zinc Co., 558 tons; Empire Roasters, 580 tons; American Zinc Co., 512 tons; Campbell Separating Co., 235 tons; a total of 378 cars with 15,000 tons, showing an average carload lot of 40 tons. More high-grade ore cleared during the month than is usual for this field.

JOPLIN, MISSOURI

MINING ACTIVITIES STIMULATED BY HIGH PRICE OF ZINC, AND LARGE SALES OF ORE. NEW PROPERTIES OF J. M. SHORT

The sharp advance in the price of zinc ore which reached $65, basis 60%, blende at the beginning of February, has stimulated unusual activity throughout the district. New derricks are going up in every camp, and some larger development is in progress. One or two new concentrating plants are contemplated on leases that have already been developed. Every prospecting drill rig is in demand, and work is being done in virgin regions. The zinc ore prices at the beginning of February were the highest ever paid, being 50c. stronger than the previous high record of $64.50, basis, paid in September, 1912. Zinc metal prices were much higher in London than ever before, quotations of £37 being reported while the previous highest was £29 10s. in 1906. New York metal reached $7.50 to $7.90 while the highest previous price was $7.65, in 1912. Production of zinc-blende from this district is about 5200 tons, and doubtless will increase to about 6000 tons in the course of a few weeks, as many producing mines that have been operated on single shift will more than double their output. Several companies that had been holding their ore for higher prices are making heavy sales. The Mont B. Mining Co., north of Webb City, began holding ore two years ago, and the pile has reached approximately 5000 tons, the greatest reserve pile of ore ever accumulated in the district. During most of this time this ore was accumulating, prices were much below $50, basis, and sometimes below $40. The value of the pile now is placed at $300,000, and a heavy tonnage of it has been sold at existing prices.

The former operator, J. M. Short of the Sitting Bull and Pocahontas mines, north of Joplin, has recently opened some new claims which appear to be rich. The Sitting Bull and Pocahontas were considered the richest soft-ground areas developed in the past 10 years in any part of the whole district. Within the past few months, however, Mr. Short has developed what is known as the New Geronimo lease, the fee of which, consisting of 40 acres, is owned by the Short Land Mining Co. A concentrating plant of 150-ton daily capacity, run by gas engines, is now in operation, and the concentrate produced is running as high as 63% metallic zinc, thus bringing a premium of $3 per ton above the prevailing basis price. The new mine is situated five miles northwest of Joplin in what is known as the Belville camp. Many years ago the property, which is in a low-lying creek valley, was mined at shallow depths and rich deposits of lead were found, but because of the heavy volume of water encountered at shallow depth, it was impossible to mine deeper although a number of drill-holes had revealed ore beneath the level of the mines of those days. Mr. Short drilled the lease to prove the old prospect holes and found that their richness had not been exaggerated. He placed 12 prospect holes on the ground, ore being shown from a depth of 30 down to 105 ft. Two new shafts were then sunk, one of which is used for pumping in which two large centrifugal pumps have been installed, the capacity of each being 1500 gal. per minute. The double installation was made in order that one unit could be used as an emergency. The ground has been drained to a depth of 95 ft., drifts are into good ore and a third shaft, to be connected with the mill by inclined tramway, is now being sunk. In addition to this property, the owner has acquired a first lease from the landowner of the Pocahontas lease, which was such a heavy producer, and has the right to remove the old pillars which contain rich ore. The ground at the Pocahontas was permitted to fill with water about a year ago, at the time when fire broke out in the heavy timbers. The old shafts were sealed at the top, and have never been reopened. It is not known in what condition the old drifts were left as a result of the fire, but this question will be settled by the sinking of a new shaft in virgin ground west of the former workings.

THE MINING SUMMARY

The news of the week as told by our special correspondents and reflected by the local press.

ARIZONA

Cochise County

As copper averaged over 13c. per pound in January, the Copper Queen and Calumet & Arizona companies, at Bisbee, fixed the wage scale for February in accordance with their promise. The Hoatson shaft of the latter property is again in operation, having been closed since August.——Eighteen gold claims in the Bowie district have been sold by T. Quillan to T. K. Mitchell, of Wilcox, for $30,000. A three-stamp mill is being erected.——The Commonwealth mine at Pearce continues to show good results from development. At 300 ft., 100 ft. from the C shaft, the Smith vein is 5 ft. wide, worth $42.75 per ton. It is hoped that the February tonnage will be about 10,000.

Greenlee County

The Shannon mine and smelter at Clifton are to be started again as soon as possible. The Shannon-Arizona railway is being repaired for resumption of traffic.

Yavapai County

Three carloads of ore from the Great Belcher mine have been sent to the smelter at Humboldt. This ore was really a large sample to test its real value. Open-cut mining is planned for the future, also a 200-ton mill to treat the gold ore.——W. W. Lewis is superintendent. The Emporia mill started on January 29.——The Excelsior claims, near Prescott, are giving satisfactory results.——A long shoot of high-grade gold ore has been opened in the Little Jessie at Chaparal. In this same district a new vein was cut in the Union claim. ——Foundations are being prepared for the Gray Eagle Reduction Co.'s plant at Crown King. Some of the machinery is on the ground.——Considerable apparatus has been ordered for the Fortune mill being erected in the Big Bug district. ——If copper remains steady, ore extraction is to be resumed from the Copper Basin and Snoozer mines of the Commercial Mining Company.

CALIFORNIA

Amador County

The Central Eureka company has paid a dividend of 2c. per share, equal to $20,000.——The old Hayward mine, three miles from Ione, is being reopened after 50 years' idleness. At 300 ft., $6 to $28 copper-gold ore has been cut.

Following is the preliminary report of output and costs of the Plymouth Consolidated for January: ore crushed, 10,800 tons; value of output, $49,991; working expenditure, $23,685; development, $7268; surplus over these charges, $19,038; and other capital expended, $616.

Butte County

In the suit of the Leland Stanford University trustees *v.* the Butte Creek Consolidated Dredging Co., an agreement has been made by which the plaintiff receives $300, and dredging will be continued.

Mariposa County

(Special Correspondence.)—The Queen Regent Merger Mines Co. of San Francisco last August bought a large group of claims over a mile long and about one-half mile wide, situated about three miles southeast of Mariposa, on which development work has been steadily carried forward by sinking prospect shafts and the driving of adits. The Company reports opening rich sulphide gold-copper ore at water-level in shallow shafts of 30 to 40 ft. depth. The heavy flow of water could not be handled without placing expensive machinery equipment, so the general manager, J. E. Kerr, advised the directors that by driving an adit about 1000 ft., four veins would be cut which would give 300 ft. of backs above the level on the No. 1 vein, and about 800 ft. on the No. 4 vein, which would afford drainage for a large area and save heavy development expense and cost of machinery. An adit was started, which has already been driven 335 ft., and the face is now in the iron foot-wall of the first vein, in which crevices occur showing particles of native copper and quartz containing gold in fair amounts. As the first vein at the surface is from 12 to 30 ft. wide, showing high copper and gold content, the Company states that if at adit level the vein shows the same width and value as at the surface, it will result in opening a large body of highly profitable ore. About 300 ft. ahead of the present face of the adit the second vein occurs, on which a shaft sunk to 40 ft. encountered water. This vein is a bold outcrop of hematite, and the ore taken from the shaft contains 6.3 to 23% copper and about $1 gold per ton. Operations of the Company are attracting considerable interest, as it is the first attempt systematically to develop at depth the copper veins of this district.

Mariposa, February 1.

Nevada County

Rich ore is reported to have been cut at 4800 ft. in the Empire mine.

Shasta County

The Mountain Copper Co.'s smelter at Martinez, Contra Costa county, is being blown-in after a shut-down since August. The Iron Mountain mine has also been reopened. The new mill and sorting plant is nearly completed.

Sierra County

So far about 50 ft. of the rich shoot has been opened in the North Fork quartz mine at Forest City. G. F. Stone is in charge.

COLORADO

Eagle County

Owing to litigation, the Lady Belle silver mine has been closed for several months, but R. A. Messa has secured a lease and resumed work. Some good ore has been opened recently.

Lake County (Leadville)

Considerable activity prevails at the larger properties of the district, including the Colonel Sellers, Yak, and Western. These are extracting large tonnages of carbonate and zinc sulphide ores.——Some rich gold-silver-lead ore has been opened in the Gordon-Tiger in the Twin Lakes district.——The new electric hoist has arrived at the Big Four.——The old Antioch mine on Breece hill, adjoining the Nome gold claim, is to be reopened by Leadville people. It was formerly worked through a 3200-ft. adit.——Mines on Breece hill are producing about 750 tons of ore per day, and the railroad is very busy.

San Miguel County

The snowslide season is now due, and on January 31 the first slide carried away two towers of the Black Bear tramway. ——The Primos Chemical Co. has 45 men in its mine in the Daily district, and according to the manager, Harold Boericke, the plant at Vanadium is soon to start again.

TELLER COUNTY (CRIPPLE CREEK)

The output of Cripple Creek in January was the highest for 10 years, due to the rich ore from the Cresson mine, where further discoveries are being made. The yields were estimated as follows:

	Tons	Average.	Total.
Smelters	4,500	$166.11	$ 747,500
Golden Cycle	29,000	20.00	580,000
Portland (Colorado City)	8,500	19.50	165,750
Portland (Cripple Creek)	16,000	3.12	49,920
Stratton's Independence	9,400	4.56	42,864
Colburn-Ajax	3,250	7.00	22,750
Gaylord-Dante	1,400	2.50	3,500
Kavanaugh-Jo Dandy	1,400	2.00	2,800
Neville-Free Coinage	600	4.00	2,400
Wild Horse	600	4.00	2,400
Isabella	1,000	2.00	2,000
Total	75,650		$1,621,884

At 1860 ft. in the Vindicator mine, the Christmas vein has been cut, showing 4 to 5 ft. of rich ore.——Construction of the new building and plant for the El Paso is well under way.——At the Aileen, between the Mary McKinney and Chicken Hawk, old workings are being repaired, and a compressor plant installed.

IDAHO

SHOSHONE COUNTY (COEUR D'ALENE)

The increase in the price of spelter has made mining more interesting in the Coeur d'Alene, and companies are 'crowding' their output.

The Stewart Mining Co., of Kellogg, will distribute 10c. per share, or $123,836, on February 20. This makes a total of $1,424,083. New orebodies have been opened below 600 ft. The Company has acquired the Old Sport copper mines on Vancouver island.——In the Silver Cable is a shoot of ore 300 ft. long and 20 ft. wide of milling grade, in which is 80 ft., 6 ft. wide, averaging 47% zinc.——As the Montana Power Co. will be able to supply current on Beaver creek about July 1, in place of April 1 as stated recently, the Oregon-Washington Railroad & Navigation Co. may build an electric line in the Sunset district. This would aid shipments from the Interstate-Callahan mine.

The office of the *News* at Kellogg was destroyed by fire on January 25, the loss being about $8000, with only $3800 insurance. No issues will be missed, as *The Wallace Miner* has lent its plant for publication.

The Success company, operating near Wallace, has opened a large body of ore at 900 and 1100 ft. The daily output of zinc ore is 100 tons, and 120 miners are employed.

MICHIGAN

HOUGHTON COUNTY (THE COPPER COUNTRY)

Present production of the mines of this district is estimated by *The Daily Mining Gazette* as follows:

Name.	Daily rock tonnage.	Mo. output refined copper, lb.	Percentage of normal.
Baltic	1,400	728,000	100
Trimoun'ain	1,300	540,800	100
Champion	2,700	1,474,200	100
Victoria	300	93,600	100
Mohawk	2,500	1,300,000	110
Allouez	1,600	510,000	75
Isle Royale	2,200	750,000	85
Osceola	4,050	1,265,000	75
Wolverine	1,700	800,000	100
Centennial	500	168,750	65
Mass Con.	800	421,200	100
Superior	700	280,000	75
Calumet & Hecla	8,000	4,500,000	75
Quincy	4,000	1,560,000	85
Winona	200	104,000	50
Ahmeek	2,500	1,200,000	75

The report of the commerce through Portage Lake canal in 1914 shows a total of 1,900,588 short tons of freight, valued at $70,010,151. This is a decrease compared with former seasons.

At the Mohawk, No. 6 shaft is down 1100 ft., and a large tonnage of 'rock' is showing in this area. The mill is producing copper at the rate of about 15,000,000 lb. per year.——At the Calumet & Hecla company's White Pine mine, a heating plant is being installed in the new mill. In three shafts there are 14 machine-drills at work.

Resumption of full time at the Calumet & Hecla and its subsidiaries was ordered on February 5.

KEWEENAW COUNTY

It is reported that some old properties near Copper Harbor are to be prospected this summer. Diamond-drilling was done there in 1909 and 1910. This place is a beautiful holiday resort.

MONTANA

SILVERBOW COUNTY

'The Water Resources of Butte' is the subject of *Water Supply Paper* 345-G of the U. S. Geological Survey, by O. E. Meinzer. The discussion covers 125 pages and is illustrated with maps, etc. The district is one of the important mining centres of the United States and has a population of over 50,000. It is situated on the north side of a small rock-bound basin in the mountain region of western Montana, with an area of about 130 square miles. The average temperature is 42°F.,

ARTIFICIAL CANYON MADE OF SLAG AT BUTTE, THROUGH WHICH SILVERBOW CREEK FLOWS.

and rainfall 13.89 in. The author describes the geology, valley fill, soil, vegetation, climate, surface waters, water in bedrock, quality of water, water in valley fill, yield of wells, irrigation, and public supply. The daily consumption is 9,000,000 gal., including that used by mines, railroads, and other industries. The Butte Water Co.'s plant is valued at $4,513,000. Large consumers are charged from 20 to 50c. per 1000 gallons.

The report of the North Butte Mining Co. for the quarter ended December 31, 1914, gives the following information: Development totaled 1874 ft., and skip-chutes cut 16,700 cu. ft. Ore reserves were maintained at the usual tonnage. High-

grade ore was found in the Edith May vein at 2800 ft. The mine was worked at 50% capacity, and costs were no higher than formerly. There was treated 50,858 dry tons of ore and 6.6 tons of precipitate, yielding 3,466,483 lb. copper, 194,585 oz. silver, and 176 oz. gold. Copper and silver on hand are valued at $1,074,819, against which are advances of $551,343. The surplus and reserve is $3,141,771. At the Granite Mountain shaft the 2600-ft. station was finished, and nearly all chutes to 2800 ft. are ready. The electric hoist is being installed and should soon be ready.

NEVADA

Elko County

(Special Correspondence.)—The Dome Mining and Reduction Co. is operating at Bullion. Work in timbering old adits, drifts, and stopes was started early in May 1914, and development to January 1 totaled 950 ft. The first ore shipment was made on June 30, and to December 1, 1814 tons of silver-lead-copper ore, worth $57,053, was sent to the United States company's smelter at Midvale, Utah. The ore is hauled 12½ miles in auto-trucks to Raines siding on the Eureka Nevada line, and transferred to the main road at Palisade. On account of the metal markets and winter, ore shipments have been suspended. An average of 10 men was employed, there being 6 at present on No. 3 and No. 4 levels.

Bullion, January 25.

Esmeralda County

The estimated production of the Goldfield Consolidated Mines Co. in January is as follows: ore mined, 30,563 tons; gross extraction, $414,000; operating expenses, $182,000; and net realization, $232,000.——Some rich gold-silver has been opened in the Klondyke district midway between Goldfield and Tonopah.

Humboldt County

Bullion output of the Seven Troughs Coalition in January was $34,000. A dividend of 2½c. per share, or $36,000, is expected on March 1. At 1300 ft. depth there is 200 ft. of ore exposed, and recently 5 ft. was opened, 1 ft. assaying $1200, and the balance $160 per ton. The new 100-ton mill should be at work in a few days.

Lyon County

The old Western Nevada copper mine has been purchased by the Nevada-Douglas company. Prospects are said to be good.——A 100-hp. gasoline hoist and other machinery recently passed over the Copper Belt line for the Pittsburg-Liberty mine at Masonic.——Some rich gold ore has been opened at 180 ft. in the Rescue mine.

Mineral County

Owing to alterations and overhauling, the Aurora mill will be shut down for about 60 days.

Nye County

Six mines at Tonopah produced 10,372 tons of ore, worth $212,656, during the week ended February 6.

The Merger has joined the shipping list and sent 100 tons to the West End mill. At 1170 ft. the vein is 6 ft. wide, assaying over $30 per ton.——The Extension's yield for the second half of January was 102,000 oz. silver and 20 tons of concentrate, valued at $68,000.——At a meeting of the Dexter White Caps Mining Co., of Manhattan, the shareholders decided not to sell out to the Tonopah Mining Company.

NEW MEXICO

Grant County

(Special Correspondence.)—The Burro Mountain Copper Co., at Tyrone, has finished with its 50-ton experimental mill and will dismantle it. Work is still going on at the 100-ton concentrator, situated several miles east of the mines and on a spur of the Burro Mountain branch of the El Paso & Southwestern railroad. Drilling for water continues in many places on the property.

One hundred seventy-six carloads of ore was shipped from the Lordsburg mining district during January, being more than has been recorded for some time.——The Monte Rico Mining Co. is making excellent progress on its adit at Lees peak, and by the end of March should be into ore and making shipments.——The Octo Mining Co., near the Lees Peak property, is building a boiler-house, and will soon start work on a fair scale.

About 1900 ft. of flume of the Chino Copper Co. collapsed last week owing to the weight of icicles, and a good deal of water went down an *arroyo* before the water could be turned. The Company continues to operate about two-thirds of normal capacity.

Lordsburg, February 5.

Sierra County

A custom concentrating plant is proposed by several operators at Kingston.

Socorro County

(Special Correspondence.)—Mogollon has suffered from lack of fuel oil and supplies, and several mines and mills have closed down temporarily.

The Ernestine Mining Co. continues to operate its mill and is shipping bullion to New York. A modern chemical laboratory is being built, and it is said that a new shaft is to be sunk. The most noteworthy development made in the district for many months is the deep exploration of the Last Chance vein by this Company. On No. 5 level, below the mail adit, which was the bottom level when the present owners took charge, and which is 1200 ft. below the apex of the main vein, a drift has already been driven into the orebody for a distance of 170 ft. The ore shows a width of 10 to 15 ft. where cross cut, and the value is above the average. A drift has also been started on No. 7 level, 200 ft. deeper, and it will soon reach the trend of this ore-shoot, which has been one of the most regular and heaviest contributors to the state's gold and silver production.

The Oaks Co. at Alma is conducting work on several different properties, and is making extensive tests on ore from the Queen vein, the mother lode of the Mogollons. Some excellent smelter returns were received from a small shipment, and development will go forward on a large scale.

The Mogollon sawmill, operated for a quarter of a century by Harry Herman, has been sold to Frank Kelly. Practically all the timber used in the Mogollons has been furnished by this mill.

The large power project of the Socorro Power & Lumber Co. is under way, and is furnishing timber to the district at a low rate. A flume is transporting lumber to the mines from Whitewater creek, and power is to be generated by water-wheels at the terminus after the project is completed. It is stated that the Socorro Mining & Milling Co. has given up its option on the Pacific mine, which was held at $250,000. An aerial tramway was under construction and a large amount of development work had been done. No reason has been given for this decision.

Mogollon, January 22.

OREGON

Baker County

The Imperial mine at Cable Cove, 11 miles north of Sumpter, has been acquired under bond and lease by the Blue Mountain Mining Co. Five veins have been opened, and reserves are estimated at $240,500. C. L. Arzeno, of Cincinnati, is manager.

SOUTH DAKOTA

Custer County

The Custer Peak Copper Co. is resuming mining, and the 250-ft. shaft will be unwatered and development started.

UTAH

Juab County

Twenty four mines at Tintic produced 430 cars of ore, valued at $555,000, in January, compared with 295 cars and $390,000 in December.

Salt Lake County

The Salt Lake City Stock Exchange has been exceptionally busy, and transactions last week totaled 338,871 shares, valued at $46,150, the largest turnover for years.

The report of the Alta Consolidated Mining Co. for 1914 shows that development totaled 2280 ft., from which 216 tons of ore was recovered, netting $4951. Prospects are encouraging, but since August the force has been reduced to a minimum.

The Utah Copper Co. started another steam-shovel last week, and has 40 more men at work.

Summit County

The flow of water from the Snake Creek tunnel is 7500 gal. per minute, and work has been temporarily suspended.——Ore production of Park City in January totaled 7824 tons, worth about $320,000, from the following mines: Silver King Coalition, 3753; Daly-Judge, 2278; Silver King Consolidated, 1460; Daly West, 243; Mines Operating (Ontario), 30; and

SILVER KING CONSOLIDATED MINE, PARK CITY, UTAH.

Daly, 60 tons. The December output was 7316 tons.

At 1800 ft. in the Silver King Consolidated the vein has been opened 500 ft. east and west, assaying 60 oz. silver and 30% lead. This level is far better than at 1700 ft.——As the Daly-Judge mill had been working its men over the regular hours, and the state labor commissioner interfered, 50 miners have been paid off. The general manager, G. W. Lambourne, stated that he had employed extra miners to relieve the labor excess supply, consequently the plant had to run longer to treat the extra ore. No millmen had complained of overtime.

CANADA

British Columbia

For the sum of $55,000, Spokane people headed by T. A. Russell, have purchased placer claims 20 miles from Vernon. Joseph W. House has been appointed superintendent. Hydraulic plant is to be ordered and installed by May 1. It will handle 3000 cu. yd. of gravel per day. This material is of high grade. A 1¼ mile ditch will supply 1500 in. of water with 202 ft. head.

Ontario

The annual report of the Crown Reserve states that the output to the end of 1914 was 18,429,141 oz. silver, of which the Carson vein yielded about half. The average price received in seven years was 54.57c., and cost 13.675c. per ounce.

A dividend totaling $240,000 was paid to Conlagas shareholders last week, making a total of $7,480,000.

The Hollinger mine produced 20,775 tons of $12.28 ore during the last 28 days of 1914. Working costs totaled $4.371 per ton, and the profit $156,059. Dividends are now $120,000 per month. The annual report shows that 208,936 tons of ore treated in 1914 yielded 1,786,680 gross profit, of which $1,170,000 was paid in dividends.——Six levels are being developed in the Dome. Diamond-drilling from the surface was stopped in December, but machines are working on No. 4 and 5 levels. The mill is increasing the tonnage treated each month.

KOREA

The Oriental Consolidated reports as follows for November 1914: 240 stamps worked 26.4 days crushing 28,056 tons of ore. The various plants recovered $154,323. The net profit was $56,078.

The Seoul Mining Co. reports the following results for January 1915:

Stamps working	40
Time, days	29
Ore crushed, tons	6,680
Total recovery	$60,850
Operating expenses	25,850
Net earnings	35,000

MEXICO

Hidalgo

The Santa Gertrudis mill treated 13,900 tons of ore for a profit of $34,000 in December. Cyanide was short.

Sonora

Ore and bullion passed through Agua Prieta from Sonora to Arizona in January were as follows: concentrate, El Tigre, 81 tons; and Moctezuma, 4410 tons; ore, Panama, 6 tons, and Santa Rosa, 21 tons; bullion, El Tigre, 128 bars and 146 sacks of precipitate; and value of shipments: copper, ₱1,246,000; silver, ₱491,000; and gold, ₱235,600.

On account of bridges being burned between Agua Prieta and Fronteras a few days ago, about 300 American people are marooned, principally at El Tigre and Nacozari. This was done by General Calles in his attempt to cut off Maytorena's communication with the border.

The San Toy Mining Co. reports as follows for the year ended December 31, 1914:

	1914.	1913.
Gross income	$ 56,228	$317,332
Expenses	148,607	148,905
Deficit	92,379	*132,427

*Surplus.

Tamaulipas

Exports of crude oil from the port of Tampico to United States ports in 1914 amounted to 11,710,508 bbl., compared with 11,150,399 in 1913 and 5,805,476 in 1912. Notwithstanding the adverse conditions suffered by the oil companies, the exports for the year show a substantial increase over the preceding year, which was considered a banner year for the oil industry in Tampico. On January 1, 1915, there were about 20,000,000 bbl. of oil in storage in this district. At present most all of the companies have shut down their wells, allowing only those wells to flow that cannot be entirely shut off on account of their high pressure. Had conditions remained normal throughout the year, double the amount of oil would undoubtedly have been shipped to the United States.

PERSONAL

H. M. Wilson is in San Francisco.

A. H. Wickham has gone to Tepic.

W. H. Knowles is down from Sonora.

G. A. Roush was in New York last week.

J. R. Finlay was at Grass Valley this week.

George S. Rice was in Washington last week.

C. A. Rodgerdts has gone to Mazatlan, Mexico.

Gardner F. Williams arrived in California this week.

J. Ballot, of Minerals Separation, Ltd., is in San Francisco.

J. A. Holmes is visiting various mining districts in Arizona.

F. G. Cottrell will visit Butte on his way back to San Francisco.

Charles Janin is visiting the dredging fields of Colorado and Montana.

Seeley W. Mudd and Philip Wiseman were in San Francisco this week.

A. H. Lawry, of the Montana-Tonopah mine, is in San Francisco for a few days.

James Butler, the discoverer of Tonopah, was at Randsburg, California, last week.

R. B. Lamb, of Toronto, is in California and has been examining properties at Grass Valley.

H. C. Hoover was in Berlin recently arranging with the German government for relief of non-combatants.

E. P. Mathewson is expected in New York next week to attend the annual meeting of the American Institute of Mining Engineers.

W. S. Noyes, Charles F. Helman, and L. M. Parkes, of the El Oro Mining & Dredging Co., visited the Natoma dredging district last week.

Thomas T. Read is expected in San Francisco immediately after the New York meeting of the American Institute of Mining Engineers.

W. H. Harrison, mill superintendent for Stratton's Independence, Ltd., has returned to Victor, Colorado, after several months spent in the Silver City district, New Mexico.

Edgar L. Newhouse has been made first vice-president of the American Smelting & Refining Co., succeeding the late Barton Sewall. Edward Brush succeeds Mr. Newhouse, and S. W. Eccles succeeds Mr. Brush, leaving one vice-presidency still vacant.

C. A. Filteau, who has been in Japan and Korea for the past two years, has been appointed general manager for the Inca Mining & Development Co., province of Carabaya, department of Puno, Peru, and sailed from New York by way of Panama for his new post.

E. M. Breed, who for the past eight years has been district manager of the Canadian Allis-Chalmers, Ltd., with headquarters at Vancouver, has been appointed district manager for the Pelton Water Wheel Co. in that city. Previous to becoming manager for the Canadian company, he was with the sales force of the Canadian Westinghouse Co. at Montreal.

Obituary

Isabel Love Wightman, for seventeen years with the Brown Hoisting Machinery Co., died on January 25.

James Gow Black, professor of chemistry for forty years at the University of Otago, Dunedin, New Zealand, died in December.

SCHOOLS AND SOCIETIES

The Utah branch of the A. I. M. E. will meet at dinner on February 25.

Abolition of the Virginia City School of Mines, Nevada, is proposed in a bill introduced into the State Legislature last week.

The American Museum of Safety held its annual meeting at the United Engineering Societies building, New York, on February 10.

The University of Iowa *Bulletin* No. 8 contains water-works statistics of 38 cities of Iowa, with the meter rates of 70 cities, compiled by John H. Dunlap.

The Canadian Mining Institute holds its seventeenth annual meeting at Toronto, on March 3, 4, and 5. A number of interesting papers are to be read and discussed.

The Institution of Mining and Metallurgy will meet in London on January 21, February 18, March 18, April 17, and May 20. The new president is Sir Thomas Kirke Rose of the Royal Mint.

The Institute of Mining Surveyors, Western Australia, is the name of a new society in that state. Holders of certain degrees from Australian and New Zealand schools entitles licensed surveyors to membership. Kalgoorlie is the headquarters of the society, and P. G. D. Lavater, first president.

The Canadian Mining Institute, at its annual meeting in March, will be asked to make several amendments to the by-laws. The word 'province' as hereinafter referred to in these by-laws shall be interpreted to mean each of the following divisions of the Dominion of Canada: Quebec; Ontario; British Columbia, including Yukon territory; Alberta, including Saskatchewan and Manitoba; and Nova Scotia, including New Brunswick and Prince Edward island.

The International Engineering Congress meets in San Francisco on September 20 to 25. The technical success of the Congress is now well assured. Notwithstanding the difficulties arising as a result of the present European war, the committee on papers is able to count on from 200 to 250 papers and reports, covering all phases of engineering work, and contributed by authors representing some 18 different countries. The Congress will therefore be truly international in scope and character.

What's Wrong with Rand Scientific and Technical Societies, is the subject of an editorial of *The South African Mining Journal* of November 28. It said: "The sparse and disappointing attendance at recent meetings of Rand scientific and technical societies cannot be wholly attributable to the war. It is true that a great many men from the mines, including many members of the societies, are on active service, and that the leisure of those who remain is mainly devoted to drilling and special police work. These excellent activities, however, can hardly be said to explain the evident reluctance of so many members of our leading societies to spare even the two or three hours a month, which is the maximum demand they make on one's time. The reason, we believe, in the case of the larger societies lies deeper. The Geological Society, of course, never boasted a big roll of membership, and its attendances have always been composed of the select and learned few. The Institution of Electrical Engineers is a comparatively young body, and, for its years, has less to complain of, in point of its monthly musters, than any of its sister societies. The two senior societies, the Institution of Engineers and the Chemical, Metallurgical and Mining Society of South Africa, appear to be the worst sufferers in this respect."

THE MARKET PLACE

Weekly Summary of Metal Prices and Notes on the Markets.

Metal Prices

San Francisco, February 11

Antimony	.20	20¼
Electrolytic copper	15½	15¾
Pig lead	4.95	5.00
Quicksilver (flask)		$60.00
Spelter	9	— 9¼
Tin	.38	39½
Zinc-dust, 100-kg zinc-lined cases	14½	15

Both quicksilver and zinc-dust are strong and likely to advance. The range of prices in the latter indicates carload and small lots.

EASTERN METAL MARKETS

(By wire from New York.)

NEW YORK, February 11.—Copper is quiet, lead firmer, and spelter strong.

The Calumet & Arizona company has declared a dividend of 50c. per share. Superior & Pittsburg, 20c., and Crown Reserve, 3%. Unfilled orders of the U. S. Steel Corporation on January 31 totaled 4,248,571 tons, an increase of 411,928 tons compared with December.

SILVER

Below are given the average New York quotations in cents per ounce, of fine silver.

Date.		Average week ending

The silver market has been steady during the past week.——The Cobalt district shipped 837,585 oz. to London in January.——At the end of September the Jim Butler company at Tonopah had 170,600 oz. in storage, showing how a small concern has to contend with the market.——India has supported business, but the demand is less persistent than formerly.——The Hongkong government is continuing its policy of retiring large quantities of subsidiary silver, and in time it may be anticipated that there will be an end to the discount as to Hongkong coins, though even in such case the situation may easily arise where small coins will be at a premium. The real difficulty in the matter is the disposition of the Chinese people to regard silver in any form, coins as well as bullion, as a commodity, rather than as an established currency with fixed value, according to a recent consular report. To the Chinese, trained by generations of dealing in silver by weight as a means of exchange, every transaction is a barter. The possibility, and even practicability, of manipulating the market for coins just as a market for any commodity might be manipulated, are taken as a matter of course. Until this bartering in coins can be prevented there will be no freedom from currency troubles in China, and any scheme of currency reform for China or for any colony using a similar currency must have regard for this fact.

TIN

Prices in New York, in cents per pound.

Monthly averages.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

The Nevada Cinnabar Co. of Ione, Nevada, recently shipped 350 flasks of mercury to New York.

RECENT PATENTS

1,122,062.—Process of Hardening and Welding Copper. Charles Bittner, Stafford, Kansas. This process consists of heating the copper to a cherry red, and then successively subjecting portions thereof to the action of acidified hyposulphite of soda, until the whole of the surface of the copper is treated.

1,117,601.—Filtering Medium. James Edward Porter, Syracuse, New York, assignor to General Filtration Co., Inc., Rochester, New York. A rapid filtering medium composed solely of from 75 to 85% of silica-containing substance, and from 25 to 15% of powdered glass mixed therewith and fused in the mixture.

1,118,894.—Process of Producing Pure Zinc Oxide. Henry William de Stuckle, Paris, France. A cyclical process of producing pure zinc oxide, which consists in reacting upon a dissolved zinc salt with ammonium sulphite in presence of caustic ammonia or ammonium carbonate, calcining the precipitated zinc sulphate and utilizing the evolved sulphur dioxide for regenerating the ammonium sulphite.

1,124,503.—Ore-Feeder for Stamp-Mills and the Like. Edward Henry Moyle, Los Angeles, California. The combination of an inclined rotatably mounted ore-feeder table, of a hopper having its lower edge inclined correspondingly with the table, and supporting means provided with horizontal ways in which the hopper is slidable horizontally to enable it to be adjusted with its lower edge close to the table.

1,123,672. Nodulizing Ores. Niels S. Borch, Copenhagen, Denmark. The process of nodulizing ores in rotary kilns which consists in raising the temperature of the mass in a reducing heat nearly to the critical temperature, and then subjecting the mass to an oxidizing action, whereby the temperature of the mass is raised suddenly through the degree required for nodulization, without a corresponding rise in the temperature of the wall of the kiln.

1,126,182.—Method of Treating Complex Carnotite Ores. Charles W. Danforth, Youngstown, Ohio; William P. Samuels, Newcastle, Pennsylvania; and William T. Martersteck, Youngstown, Ohio. The process of treating complex carnotite ores consists of subjecting the finely reduced ore to a plain oxidizing roast, to transform the highly refractory complex carnotite ore to a condition in which it may be worked up, and recovering the valuable products from the roasted ore.

1,121,606.—Process of Treating Sulphide Ores and Other Metallic Sulphides. Kristian Birkeland, Christiania, Norway. The process of treating sulphide ores and other metallic sulphides with superheated steam for removing the sulphur, which comprises superheating the steam to substantially the temperature of a flaming arc, passing said steam through the sulphides, separating hydrogen from the resulting gases and returning it with fresh quantities of highly heated steam for treating the material.

1,122,759.—Process of Extracting Copper from Ores. Noak Victor Hybinette, Christiania, Norway. The process of electrolytically extracting copper from sulphide ores containing iron, which consists in leaching a material containing copper both in the form of sulphide and oxide, with an acid sulphate solution containing iron to an amount of 25 to 35 gm. per litre as ferric and ferrous sulphate, electrolyzing the resulting solution and interrupting the electrolysis when 10 to 20 gm. of iron is present as ferric sulphate.

1,125,897.—Process of Concentrating Ores. John M. Callow, Salt Lake City, Utah, assignor to Metals Recovery Co., Augusta, Maine. The process herein described of breaking down and discharging the froth, foam, or suds, accumulating on the surface of an aerated and agitated mineral-bearing pulp containing a frothable agent having a selective affinity for metalliferous particles, said process consisting, essentially, in producing in a vessel open to the atmosphere a difference in pressures between the inside and outside of the air bubbles forming the froth, foam, or suds, and conducting the fluid contents of the broken down bubbles and mineral particles thereof to a receiver.

1,125,480.—Mine-Drill Support. Howard P. Corsa, Bingham Canyon, Utah. A drill support comprising an extensible horizontal bar, a second bar, a block bolted to the second bar, and slidably and pivotally holding it on the first, said block being provided with a cut-away portion adjacent to the first bar, a second block seated in said cut-away portion and adapted to engage the first bar and means supported in the first block and engaging the second to force said second block against the bar.

1,124,528.—Mining Machine. Lige Robinson, Empire, Alabama. This machine comprises an imperforate tubular drill having a circular bit at its outer end, a feed screw extending through the drill and having means at its forward end to engage the material being drilled, said feed screw being smaller than the inner wall of the tubular drill to allow a space to receive material bored out, a feed nut to move on said screw and connected with the tubular drill to move with the same and means for rotating the feed nut and drill.

1,123,116.—Amalgamator. James P. Dovel and Charles C. Glidden, Birmingham, Alabama. An ore concentrator comprising a rotatable concentrating-table having a series of annular grooves therein containing each a body of mercury and disposed transversely to the line of flow of the material to be treated, said table having non-amalgamated surfaces interposed between the grooves, and said grooves having amalgamated surfaces with which the mercury therein contacts and which tends to prevent the globularization of the mercury while in the grooves.

1,116,642.—Method of Concentrating Ores. William Sydney Stevens, Magdalena, New Mexico, assignor, by mesne assignments, to the Ozark Smelting & Mining Co., Cleveland, Ohio. The process of concentrating ore, which consists in mixing together at a temperature of not less than 60° C. crushed ore, sufficient water to form a flowing pulp, sulphuric acid, and a mineral oil in amount only sufficient to preferentially coat the desired sulphide particles of the ore; and thereafter presenting the pulp to the air and then to the surface of a liquid to cause a flotation of the oiled sulphide particles by surface tension.

1,123,778.—Precipitating Metals From Solutions. Louis David Mills, Johannesburg, Transvaal, South Africa, assignor to Merrill Metallurgical Co. The process of precipitating metals from their solutions which consists in maintaining a homogeneous mixture of said solutions and a mobile precipitant at the surface of a filter medium, withdrawing solution through said medium whereby the solid matter suspended therein is deposited as a homogeneous and uniformly permeable layer on said medium, and circulating the excess mixture adjacent to said filtering medium.

1,118,944.—Process of Recovering Rusty Gold and Native Platinum Metals. R. E. Lyons, Bloomington, Indiana. The process of recovering precious metals consisting in adding to material containing particles of precious metal in a condition that will not normally amalgamate, a metal capable of alloying with the precious metal at normal temperatures, metallic mercury in quantity sufficient to form a substantial amount of amalgam, and a substance capable of attacking the alloying metal, such attacking substance being in quantity sufficient to maintain a continuous reaction during amalgamation of the precious metal.

New Machines and Devices

Motor-Driven Mine Pump

The illustration shows a group of motor-driven pumps developed especially for sump and gathering service in coal mines. These pumps have brass-lined water cylinders, tobin bronze piston rods, and bronze valve-seats, stems, springs, stuffing box-caps and glands, and bronze adjustable cross-head shoes, so that they are thoroughly protected against the action of mine water. The motors are direct-current Westinghouse Electric manufacture, and they are mounted on top of the

MOTOR-DRIVEN MINE PUMPS READY FOR SHIPMENT.

pump, where they are kept out of the water, and are supplied with impregnated windings, which afford protection from dampness. A special feature is the use of automatic control by which the pump can be started and stopped from any convenient point. The unit formed by motor and pump is very compact, and is readily mounted on a truck, so that it can be easily transported from place to place as needed. The group shown is a lot ready for shipment one week after receipt of order. The maker is the Weinman Pump Manufacturing Co., Columbus, Ohio.

The Marathon Mill

The Johnson Engineering Works, Chicago, Illinois, has devised, tested, and is supplying a machine called the Marathon mill. The apparatus has been installed in the plant of the Detroit Copper Co., Arizona, and the following are some features claimed by the makers: The Marathon mill is of the revolving cylinder type, but unique in that the grinding is done by a charge of round steel grinding rods, of different diameters and the full length of the machine. The material being ground completely, fills all the spaces between and is confined by the near contact of the bars so it cannot escape. This confinement of the material, together with the great weight of the rods on it and the revolving motion of the drum keeping all the rods in constant motion, causes most of the grinding to be done by attrition of the material on itself. This accounts for the small amount of wear on the steel grinding bars per ton of material ground. Another feature of the Marathon is that practically all of the grinding bars are used up in actual work. Starting, say with rods 5 in., they should be withdrawn when worn down to about ¼ in. diameter. The Marathon, without any alteration, is a wet grinder when water is added with the feed; otherwise it grinds dry, or with any percentage of moisture the feed may contain. It is a continuous feed and discharge machine, and is therefore a great improvement over the dry or wet pan pug mills for brick making, and other uses. The capacities shown, of from 245 to 540 tons per 24 hours for a mill taking only 18 to 19 hp. and grinding through different screens, is remarkable.

The Rise of Steel Pipe

There is a real romance in the rise of steel pipe in the last eight years, from 983,198 tons in 1905 to 2,189,218 tons in 1913, when, during the same period, wrought iron pipe decreased from 452,797 tons in 1905 to 312,746 tons in 1913. The percentage of iron pipe in 1913 was 12.5, and steel pipe 87.5. There is another phase of this which may probably be of interest, namely, the greatly increasing use of steel pipe in the world for gas and water mains. It will be noted in this connection that this use is not so much confined to the United States as it is to foreign countries. The National Tube Co. of Pittsburgh, *Bulletin* 11-C, of 48 pages, deals with the history, characteristics, and advantages of 'National' pipe. Early methods of pipe manufacture, from the bamboo, pottery, and lead tubes, to the present high-grade type are explained.

Most Powerful Dipper Dredges in the World

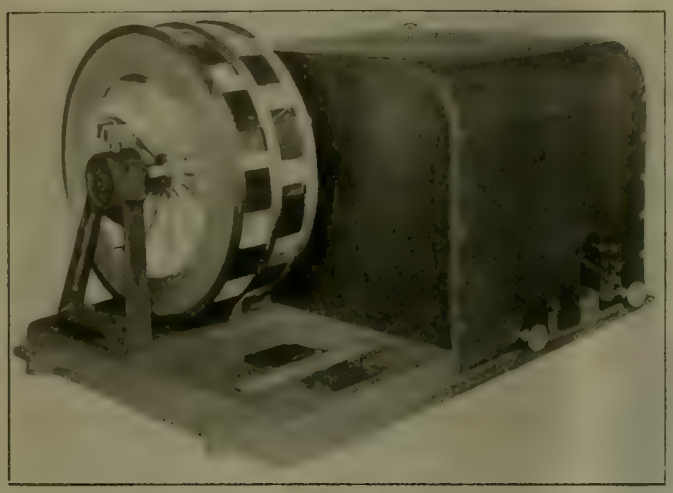
Dipper dredges of large capacity are needed at the Panama canal, and the accompanying illustration shows the *Paraiso* in Culebra cut, lifting a 50-ton boulder. This boat and the *Gamboa*, of Bucyrus Co. manufacture, were partly constructed on the Hudson river at Newburg, New York, towed to Staten island, completed, and tested. The booms, dipper handles, and dippers were taken down and shipped to the

U. S. DREDGE (BUCYRUS) *Paraiso* RAISING A 50-TON BOULDER FROM BOTTOM OF CULEBRA CUT, PANAMA.

Isthmus, while the steel hulls were towed to Colon. Of the 1500-tons displacement of each dredge, the boom (62 ft. long) and its machinery weighs 66.5 tons, and the dipper handle (72 ft. long), 40.5 tons. Both are equipped with 15-cu. yd. dippers, and are designed to dig 50 ft. below the surface of the water. The dredges are equipped with high-power machinery, and have been handling about 125,000 cu. yd. per month with hard digging. When first started they withstood a 30-day test successfully. Boulders weighing up to 50 tons each are lifted by the dredges.

The Denver Siren

This apparatus is a motor-driven fire alarm for cities, mills, and factories, and is made by the Hendrie & Bolthoff Manufacturing & Supply Co. of Denver, Colorado. The siren creates a distinctive sound suitable for fire and general alarms, and could be operated by a switch placed alongside the telephone central's desk or any other suitable place. The revolving part



DENVER SIREN.

of the siren is made of aluminum, mounted upon Hess-Bright ball-bearings, and the outside portion, or stator, of bronze. The rotor does not touch the stator at any point and thus revolves very easily. The siren gives the best results when equipped with a three-phase induction motor. The motor and transmission are protected from the weather by a close-fitting metal hood; but the siren itself cannot be covered and is therefore made of bronze and aluminum, neither of which will corrode. Two sizes are made, 3 and 5 hp., weighing 300 and 400 lb., respectively, and the noise can be heard for six miles.

Commercial Paragraphs

The American Vanadium Co. of Pittsburgh. *American Vanadium Facts* for January devotes several pages to illustrating the types of automobiles and trucks in which vanadium steel is used.

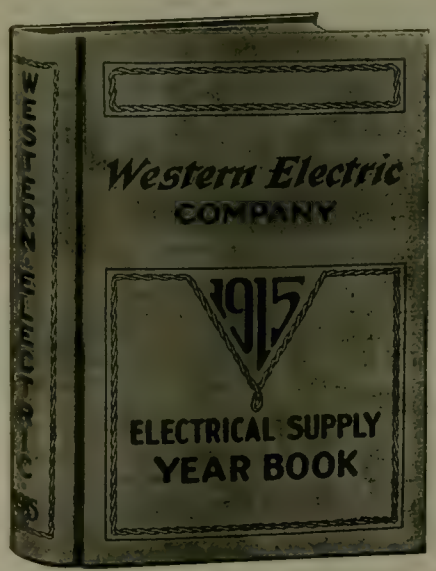
The Atlas Car & Manufacturing Co., Cleveland, Ohio, has issued *Bulletin* 1175 on 'Storage Battery Locomotives, Cranes, and Cars.' With full page and smaller illustrations it covers 32 pages. These locomotives were designed for low vein mine use, having a low and narrow frame. A generating set for charging storage batteries is also made. The total cost of such locomotives is 2c. per ton, against 4 or 5c. using mules. The storage battery tractors and cranes are also of good service.

The General Electric Co., Schenectady, New York. *Bulletin* 49,901 for January describes an oil-testing set for transformers. In order to insure the successful operation of high-tension oil-insulated apparatus, the dielectric strength of the oil must be maintained at a certain value. The Company devised a testing transformer with a capacity of 3 kva. at 30,000 volts. It can be supplied either for 25 or 60 cycle current. The low-voltage winding is suitable for service on 100, 200, or 400-volt supply. Other apparatus is attached to the set.

The Terry Steam Turbine Co., Hartford, Connecticut, *Bulletin* 19, of 64 pages with illustrations, describes its turbines for pump drives. The principles of operation and construction of the centrifugal pump are clearly explained, as are the details of the steam turbines which have been successfully used during the past 10 years for driving them. Because of the wide latitude of speed possible with the turbine, the unit occupies a much smaller space than would be required for a pump performing the same duty but driven by a reciprocating engine. The range of conditions in this service varies from large volumes of water pumped against low heads, such as circulating water for condensers or for irrigation, up to high head work, such as boiler feeding or fire service. This apparatus is made to any size. Much useful data are included in the catalogue. The Company announces that it has appointed Earl F. Scott, with offices at 702 Candler building, Atlanta, Georgia, as representative for that state; and H. A. Rapelye is now in charge of the Pittsburgh office, at 1624 Oliver building.

The Mesta Machine Co., Pittsburgh, Pennsylvania, in an attractive booklet, describes the plant and products of the Mesta Machine Co. The plant covers about 20 acres and has about 500,000 sq. ft. of floor space and over 400,000 sq. ft. covered with electric cranes. The only limit as to the size and weight of the machinery which the Company builds is that fixed by the capacity of railroad cars. Castings weighing over 100 tons have been made in the foundries and finished in the machine shops of this Company. The principal products of the Company include blast-furnaces and power plants, gas and steam engines, barometric condensers, air-compressors, iron and steel rolls, and pinions and other equipment. The booklet is fully illustrated and contains in concise form a description of the plant and the purpose of the Mesta company.

The Western Electric Co. has published its 'Electrical Supply Year Book' for 1915, the accompanying cut being a reduced facsimile of the front cover. It contains 1216 pages, and is profusely illustrated with almost every electrical device



known, and which is manufactured by this Company. The price of each article is also given, and there is given a catalogue of electrical technical books, and several pages of useful formula. In many particulars this catalogue is unusual and it will be invaluable for handy reference. This valuable publication should be in the library of all interested in electrical work.

METALLURGICAL PRACTICE in the Lake Superior copper district has many peculiarities. It is the one great district in which native copper forms the basis of operations, and this fact has made possible development of an ore dressing and smelting practice that is unique. Steam stamps dominate the field. Regrinding and concentrating follow the stamps, and probably leaching of the tailing will follow them. The smelting practice is relatively simple, but possibly open to criticism. In the PRESS for December 5 and February 6, Mr. Read discussed the occurrence and mining of the orebodies. In this issue he discusses the treatment of the ore as conducted in the newest plants, typified by the Calument & Hecla regrinding plant illustrated below and built to treat tailing dredged from Torch Lake.

MINING PRESS

Established May 24, 1860, as **The Scientific Press**; name changed October 20 of the same year to **Mining and Scientific Press**; shortened January 2, 1915, to **Mining Press.** Controlled by T. A. Rickard.

Published weekly at 420 Market street, San Francisco, by the Dewey Publishing Co., H. Foster Bain, manager. Entered at the San Francisco post-office as second-class matter. Cable address, Pertusola.

Branch Offices—Chicago, 300 Fisher Bdg.; New York, 1308-10 Woolworth Bdg.; London, The Mining Magazine, Salisbury House, E. C., London. Cable address, Oligoclase.

Price, 10 cents the copy. Annual subscription: United States and Mexico, $3; Canada, $4; other countries in postal union, 21s. or $5.

LAKE SUPERIOR COPPER MINING, PRESENT AND FUTURE—III.
By Thomas T. Read 284

In this article Mr. Read follows his discussion of the occurrence and mining of the ore by an account of the metallurgical practice in this district. The first peculiarity is the separate coarse crushing in the 'rock-houses.' This is followed by stamping and fine concentration in great mills, the principal operations being dewatering and classifying the stamp pulp, concentrating classified material on Wilfley tables, regrinding in Hardinge mills, and re-treatment on tables. Eventually the tailing will be leached. There are four smelting plants, but, in Mr. Read's opinion, smelting is the least advanced part of local metallurgical practice. Coarse crushing costs 1.5 to 8.6c.; transportation to mill, 3 to 17.5c.; stamp-milling, 18.7 to 40c.; smelting, freight on copper, and selling costs, 13.9 to 31c. per ton.

MINERAL RESOURCES OF JUJUY PROVINCE, ARGENTINE REPUBLIC.
By Arthur W Jenks 291

Jujuy province adjoins Bolivia. It contains numerous quartz veins and placers, but has little gold production. Borax and salt are important, and there are distinct possibilities of petroleum production. Mr. Jenks gives numerous practical hints on travel and exploration in the region, based both on his experience as manager of the Famatina, and later in studying the province for the Argentine authorities.

PROFITS AND HOLDINGS OF GUGGENHEIM EXPLORATION COMPANY 295

In 1914 the net income was $3,383,622, equal to 16.27% on outstanding stocks, and the dividend rate was increased from 12% to 14%, certainly an excellent record for a year of general business depression.

REVIVAL OF THE MEADOW LAKE DISTRICT, CALIFORNIA.
By W. Prince Catlin 296

Meadow Lake district was active in 1863 to 1865, but has since been nearly deserted. Within the last year the Excelsior mine has been reopened, other properties taken under option, and the breath of life breathed into the district. Mr. Catlin gives brief notes on the geology and occurrence of the ores.

THE BOSS MINE, GOOD SPRINGS, NEVADA. Page.
By Seeley W. Mudd 297

Mr. Mudd gives a short account of the occurrence of gold and platinum in limestone in southern Nevada. Such an occurrence is so unusual as to be almost unique.

PROSPECTING DREDGING GROUND AT PATO, COLOMBIA 298

An interesting abstract from a recent report by Mr. W. A. Prichard. This supplements the discussion that has been running in the *Press* on methods of prospecting placer ground.

U. S. GEOLOGICAL SURVEY EXHIBIT AT THE EXPOSITION 303

A few details regarding one of the most interesting exhibits that will be made.

ONTARIO will investigate, through a government commission, the feasibility of refining nickel matte in Canada. We discussed the general problem last week.

PIG IRON production of the United States is increasing, and the 1,591,024 tons made in January is the largest output since October, when it was 1,767,227 tons. In January 1914 the yield was 1,879,336 tons.

APPROXIMATELY once a year it seems necessary to remind contributors that we cannot accept for publication anonymous articles, though we are willing, when there is good reason, to allow the printed article to appear under a *nom de plume*. If 'Another Engineer' will send us his name and address we shall be glad to consider his letter.

WESTERN CANADA is to have another technical publication, *Mine, Quarry, and Derrick*, printed at Calgary and issued under the experienced editorship of Mr. J. C. Murray. The first number includes an excellent article by Mr. J. B. Tyrrell, on 'Gold on the North Saskatchewan River,' and other matters of interest. We salute our new contemporary and extend good wishes.

APPEALS are being made for funds for the American Ambulance Hospital, an auxiliary to the American hospital in Paris. The institution is entirely neutral and is doing what can be done to minimize the suffering incident to the war. It is in excellent hands and funds contributed will be well used. Contributions may be sent to Messrs. J. P. Morgan & Co., 23 Wall street, New York city.

CURB prices are often queer in more senses than one, and meteoric advances, followed by equally rapid drops, are registered upon the slightest occasion. Not long ago a young broker, excited over his first telephone order, which chanced to be for 1000 shares of San Toy, bid up Standard Oil, to an increased valuation of $150,000,000 before he got the name right. The announcement in the *Daily Commerce Report* that the Standard had found oil in China resulted in a rise in 'values' of $15,000,000. In fact, the amount of oil found was insignificant, though a good omen for the extensive surveys the Company is now making in Shensi.

TODAY sees the opening of the Panama-Pacific Exposition and the beginning of the period of realization following several years of preparation. It was in 1909 that San Francisco formulated definite plans for an exposition to celebrate the opening of the Panama canal. Doubtless, if the business depression, and, especially, the European war had been foreseen, there would have been no exposition; but, fortunately, the work was begun so early that the most difficult tasks had been accomplished before either arrived. The result is that on the opening day all the Exposition buildings are complete and the grounds are beautifully planted, paved, and lighted. A few of the state buildings are not open, and several foreign buildings are incomplete. Most notable is the absence of German, British, and other European special buildings such as have been features of great preceding fairs. The list, however, of states and foreign governments participating is a long and notable one, and the few unfinished buildings but emphasizes the unusual completeness of the Exposition. In many particulars the fair is unprecedented. For one thing, it is held without any appropriation from the United States government, other than the small amounts spent by various departments to collect and place exhibits in buildings furnished by the Exposition company for the free use of the government on the same terms as to any private exhibitor. For another, the main buildings and the grounds are planned as a single architectural unit, with a result that its beauty surpasses any previous achievement. Color has been used lavishly, and in the bright California sunshine, with the background of ocean and mountain, the effect is one that all visitors will long remember. It will be our pleasure to describe in detail, as the weeks pass by, the various exhibits that are of especial interest to mining men. In general, we can say that from the first day any mining engineer or metallurgist will find more than enough of technical interest and value to repay him amply for time spent on the grounds. In the Palace of Mines and Metallurgy, Mr. C. E. van Barneveld has brought together a surprising array of exhibits of processes and products. From the bottom of the mine under the floor to the top of the tallest oil derrick, the space is full of sights familiar to the men of the profession and of high educational value to the general public. Among the larger exhibits may be mentioned those of the United States Steel Corporation, Standard Oil Company, Union Oil Company, Anaconda Copper

Mining Company, the Japanese mining companies, the United States Geological Survey, the Bureau of Mines, besides which there are many others that must be reserved for later mention. We can assure our friends that the Exposition is really worth while, and we extend to all a cordial invitation to look in at the model foreman's office in 'The Mine,' equipped by the *Mining Press*. Naturally, being a model office, the *Press* itself will be found there on file.

TELEGRAPHIC advices from New York are to the effect that the proposed amendments to the constitution of the American Institute of Mining Engineers were carried by a majority of more than 500 votes. As we indicated in our editorial of January 2, this removes the bars to any expression of opinion by or on behalf of the Institute and marks a fundamental departure from long established policies. It remains for the board of directors to formulate plans for making the action effective and to devise means of securing a consensus of opinion in cases where it is desired. This is a matter of detail, but one that requires, and will doubtless receive, most careful consideration. Naturally we are pleased at the result of the referendum, since the *Press* was the only technical paper that came out frankly and squarely in favor of these changes, just as it was the only one in 1912 to advocate the changes then made in the organization. We would not arrogate to ourselves credit that belongs to the membership at large, and particularly to the group of active and unselfish engineers who have been so prominently connected with the rejuvenation of the Institute, but we are glad to have confirmation of our faith that the members of the Institute are neither so uninterested, nor so inactive, as to be unmoved by sound argument fairly presented.

FLOTATION, as applied to the saving of copper minerals, received an endorsement of the highest character this week when the Anaconda Copper Mining Company announced that it had signed a contract with Minerals Separation, Limited, for use of the process at Anaconda. As readers of the *Press* know, the staff of the Anaconda company has been engaged for several years in an exhaustive study of mill losses and in endeavoring to improve the flow-sheet so as still further to decrease them. Few American companies have put in on research problems as much time, money, and first-class skill as has the Anaconda. The Butte meeting of the American Institute of Mining Engineers in 1913 was especially notable for the contributions to technology made by the staff of the Anaconda company. As we had the pleasure of announcing in May 1913, Mr. Frederick Laist and his associates devised a plan of roasting and leaching to be applied to low-grade tailing from the wet mill, and since then a 2000-ton plant has been built to employ this process. Later Mr. L. D. Ricketts recommended that flotation be tried as an alternative or supplementary process, and an experimental unit has now been in operation for nearly a year. The results have been so satisfactory as to surpass the requirements laid down by the Company at the beginning of the test. Detailed figures of recovery and cost are not yet available for publication, but the contract made with Minerals Separation permits general use of the process. The plant, which will be built immediately, will consist of 24 units of 100 tons per day capacity each. This will be employed upon current material, and it is expected that the leaching plant will be worn out on accumulated tailing. If the working plant proves as satisfactory as is anticipated, additional units will be erected. The cost of the copper won by the new plant has been said to be as low as four cents per pound. If this be the correct figure, there will be an excellent profit realized, since the copper is won from material previously untreated. The four cents does not include the ordinary charge for mining and milling, which is proper enough under the particular conditions. Another phase of the matter that is significant is that the Anaconda company takes a license from Minerals Separation despite pending patent litigations. This is recognition of which that Company may well be proud.

THE WAR AND JAPAN

Underneath the circumstances which led directly to the outbreak of war in Europe can be clearly seen the economic considerations which are its fundamental causes, but with which we here have nothing to do. The small and widely scattered colonial dependencies of Germany were quite easily seized by her adversaries, but the more difficult task of reducing Kiaochow fell to Japan, with England's co-operation. This was a German protectorate, with an area of 200 square miles, on the east coast of the province of Shantung, which was formally leased until 1998 to Germany by China as compensation for the murder of two German missionaries. Surrounding the leased zone is a neutral area of 2500 square miles in which Germany had certain privileges which gave her commercial advantages. The German government spent considerable sums in fortifying the seaport of Tsingtao, at the terminus of the railroad connecting with the interior and the main line between Nanking and Tientsin, and in improving the harbor until it became one of the best of the few good harbors in China. These improvements and privileges now have passed into the hands of Japan, which will undoubtedly retain them. Some of the economic advantages which will accrue to that country are obvious, others may require further explanation.

It has always been the ambition of Japan to hold in the Pacific the position which Great Britain holds in the Atlantic. Unfortunately she lacks two of Great Britain's national assets: coal and iron. Japan has no iron ore deposits of importance, and her coalfields, while yielding a large present output, are limited in extent, so that it can be clearly seen that at the present rate of mining the coalfields will be exhausted at no very distant date. One estimate of the coal resources of Japan

corresponds to less than ten years of the present annual production of Great Britain. The government iron works at Wakamatsu has been operating for years on imported iron ore and pig iron, chiefly from China, and the unfavorable position Japan might occupy in the event of war doubtless has been a source of concern to her far-seeing statesmen. As a result of the series of events following the war with China in 1894 and with Russia in 1904, Japan has now secured possession of Korea and a lease on the southern half of Manchuria extending to 1923. Intelligent prospecting work has disclosed iron ore deposits of fair quality in Korea; the ore from these is already being shipped to the plant at Wakamatsu, and a blast-furnace will soon be erected in Korea to produce pig iron for shipment to Japan. Manchuria has proved even more productive. The coal mine at Fushun, which was worked in a small way by the Russians, has proved with adequate development to be one of the big mines of the world, and this one property will yield over 100,000,000 tons of coal, a notable addition to the resources of Japan. At Pensihu both coal and iron ore occur. Coke ovens have been erected and the first of the blast-furnaces was to have been in operation this fall, while two more have been contracted for. This is just the beginning of developments by which the economic position of Japan has been greatly improved. If now there is added to this the lease on eastern Shantung a further improvement will be made. The Germans had the right to develop mines for 10 miles on each side of the railroad from Tsingtao to Tsinanfu, and although their ventures at Fangtze and Poshan have not so far proved profitable, it is quite probable that valuable mines may in time be developed. A great variety of minerals have been reported from Shantung and there are two gold mines of great promise which have not been worked for a variety of reasons not connected with their richness. Quite a few diamonds are picked up in Shantung each year, and the province may prove very productive of mineral wealth if intelligently developed by good business methods.

Hotheads in this country and Japan continually harp upon the possibility of war between the two countries, like small boys who, by discussing the possibilities of a fight between two of their comrades, hope to bring about the fight which they desire to witness. There is no adequate reason for a war between this country and Japan. Such sources of irritation as have at times existed are merely minor affairs which should be adjusted in a less destructive way. As to economic rivalry in the Pacific, the conflict of our interests with those of Japan is entirely too slight to lead to a war. Our trade with China is too small to warrant attempting to protect it at the cost of a war, with its corresponding possibilities upon our trade with Japan. As to our attempting to check Japan in her expansion on the mainland of Asia, there are three good reasons against such a course. The growth of Japan's influence on the mainland is the effect of natural economic forces, which can scarcely be opposed, and only at great cost. Public sentiment here does not support such a course of action, and the advantage to be gained is too little in comparison with the cost. Finally, the relations between foreign countries are none of our business; no one has yet constituted us an international policeman. Our true interest lies in a working alliance with Japan which will safeguard and foster the mutual interests of the two countries in the Pacific, and no time should be lost in bringing it about.

WAR'S MENACE TO THE COPPER INDUSTRY

The immediate effect of the European war upon the copper mining industry has been a restriction of foreign markets for the metal, which has been fully discussed in previous issues. This has its serious features, but it should not be allowed to obscure the fact that the war may have an ultimate effect which, if it eventuates, will have much more serious consequences than the temporary difficulties with export shipments that now engage the attention of producers. The possibility arises out of the simple fact that copper is now selling in Germany at 35 cents per pound and is likely to go higher before the end of the war. This high price of copper will, of course, stimulate the opening of copper mines in Germany which could not be worked at a profit in competition with cheap American copper, and some of these mines, once equipped, will doubtless be able to continue to operate when normal conditions of trade are restored. This is but a minor matter, the great danger lies in the possibility that the German people through having to get along with a decreased supply of copper for a considerable period may learn how to do it permanently, and the practice may spread to the rest of the world. When France was cut off from trade with the rest of the world by the Napoleonic wars, French chemists set to work with high zeal to learn how to make France economically independent, and from their labors a large part of the distinctly modern science of industrial chemistry arose. When we speak of the scientific achievements of LeBlanc, Berthollet, Gay Lussac, Thenard, and Dulong we are apt to forget the influence which the wars of their day had on their scientific labors.

The patient industry of German chemists and metallurgists is almost a proverb. A shortage of copper in Germany is equivalent to saying that many brilliant minds are at work on the problem of devising substitutes for copper or bringing about changes in engineering practice which will decrease the need for that metal. Aluminum is already a competitor of copper for electrical transmission. The Aluminum Industrie Aktien Gesellschaft produced 33,000,000 pounds of aluminum in 1913; what could be more desirable from the German viewpoint than to increase the consumption of the product of a German company and decrease the imports of foreign copper?

The rôle of a prophet is always a dangerous one, but it seems clear that copper producers would do well to consider the possibility that one outcome of the war may be to decrease the consumption of their product.

Lake Superior Copper Mining, Present and Future—III

By THOMAS T. READ

Metallurgical Practice

In the two preceding articles I have briefly considered those factors in the character and occurrence of the Lake Superior copper deposits and the methods employed in their exploration and mining which seem most significant as regards the present and future prosperity of the district. It remains to take up next the metallurgical operations and consider them in the same way. Of metallurgical operations three sub-groups may be distinguished; the preliminary crushing and sorting of the ore at the shaft head; the separation of the copper by wet concentration; and the smelting of the concentrate. It will be well to discuss these in order. I shall here, as previously, assume that my readers are familiar with the general features of Lake Superior practice, which have been clearly described by T. A. Rickard in his 'Copper Mines of Lake Superior,' and will confine my discussion to only those features which bear on my theme—the trend of progress and its probable effect on the future of the district.

Coarse Crushing

The ore from the mines is hoisted in Kimberly skips holding from 5 to 10 tons. The shaft-houses, locally known as 'rock houses,' are all much of the same design, as will be evident from the illustrations in this and the preceding article, but differ a good deal in detail. The path followed by the material after it is discharged from the skip is illustrated by the diagram, already used* and taken from an admirable paper on the 'rock house' practice of the Quincy Mining Co., presented before the Lake Superior Mining Institute by T. C. DeSollar. The diagram illustrates the practice at the Copper Range properties and is typical of the district as a whole. At the Quincy No. 2 an improved practice is in vogue. Thus, for example, the dull drills brought up from below in the skip are gently slid out upon an inclined apron, from which they can be easily loaded upon a wagon and taken to the blacksmith shop. Thus the labor cost and delay of throwing the drills out of the skip by hand are done away with and there is less breakage of the steel; the throwing of it a considerable distance into a confused heap being as much of a strain on the steel as actual service. This arrangement is typical of future progress; it is by just such attention to details that unnecessary labor is being eliminated and costs decreased so as to permit the cheap and efficient work on a large scale which must characterize the district if it is to achieve its destiny of long life and large production with a small working profit reaped from low-grade material.

The operations which go on in the shaft-house appear somewhat complicated at first glance, but they are all necessary. It must never be forgotten that the copper occurs in pieces of microscopic size, and from that up to masses weighing several tons, the upper limit of the size of piece hoisted being the weight which can be loaded into the skip underground. If such a piece is quite free from adhering rock it is discharged at the same place as the dull steel and sent directly to the smelter. Masses which contain adhering rock are dumped over the grizzly like ordinary ore and lifted, usually by the aid of an air-operated hoist, beneath a heavy drop-hammer, commonly also actuated by air, where the adhering rock is broken away by heavy blows and the copper mass then sent to a bin or platform whence it can be sent to the smelter.

The undersize of the grizzly goes directly to the bins, from which the railroad cars are loaded, the oversize discharges into the upper bin, from which it is drawn out on the feed plate of the jaw crushers. Here again any large masses of copper are picked out and freed from adhering rock by the blows of a smaller air or steam hammer. The final product of the 'rock house' operations is, therefore, ore crushed through a 4 to 6-in. ring and mass copper, the one being sent to the stamp-mills and the other to the smelter. The purpose of these operations is to insure that no mass of copper larger than 5-in. diameter shall find its way into the mortars of the steam stamps. The necessity for this will be more evident when I come to consider the operations of concentration. Incidental to this work a small amount of waste is picked out and thrown away, but it may be questioned whether there is much economy in so doing. The cost of transporting such material to the stamp-mills only averages 14c. per ton, and the cost of putting it through the mill 21c. per ton, a total of 35c. per ton, which is probably little if any greater than the cost of picking it out and disposing of it. To this view may be opposed the argument that the attendance in the 'rock houses' has already been reduced to a minimum and the men may as well pick out the waste as to allow it to proceed, while the cutting down of the tonnage sent to the stamp-mills allows both the railroad lines and stamp-mills to handle a correspondingly large quantity of richer material. It may be tentatively concluded therefore that the picking out of waste is economical wherever it does not involve any additional labor, but that if it is ever found possible to decrease the labor required in 'rock house' crushing by abandoning the sorting out of waste, its cessation will be justifiable. As has been already hinted in what has preceded, the new concentration methods will tend to the same end, for masses in which no copper can be distinguished by the eye may yet yield a good quantity to proper concentration processes, and they cannot therefore be safely discarded.

The first impression of the visitor familiar with coarse-

*See *Mining Press*, February 6, p. 211.

crushing practice in other districts is that the scheme of operations thus outlined is uneconomical. It is necessary to have a great number of shafts, but there is no obvious necessity for an equal number of coarse crushing plants. Since the output of a number of shafts goes to a single milling plant the natural thing to do would be to construct a single coarse crushing plant, to do the work of a number of the present 'rock houses,' adjacent to the mill. The shaft houses could then be much smaller and cheaper to construct, while the cost of the coarse-crushing plant would be much less than that of an equivalent 'rock house' capacity, for a variety of reasons which at once suggest themselves, but chiefly because the coarse-crushing plant could easily be kept in continuous operation throughout the 24 hours of the day, whereas crushing operations in the 'rock house' are subject to the routine of shaft work: lowering and hoisting men, timber, supplies, and in some cases bailing out of water, so that the net operating time is not over 15 to 16 hours per day. The logic of this is unimpeachable and most of the arguments brought forward against it do not seem to have much real weight; for example, that the large masses brought up in the skips would seriously damage the railway cars and bins. The convincing argument on the other side is that the costs in some of the 'rock houses' are less than in large central coarse-crushing plants. Most of the companies do not keep, or at least report, their accounts in such a way that it is possible to determine the cost of the various steps in the production from ore, and the only companies which report the cost of coarse crushing are the Mohawk, 8.6c. per ton; Copper Range Consolidated, 5.45c. per ton; and the Wolverine, 4.9c. The most interesting feature of these figures is that the Copper Range cost is made up of 2.62c. per ton for labor and 2.83c. per ton for power, repairs, supplies, etc., having been decreased to these figures from 6.29 and 3.42c. per ton, respectively, five years previously. The labor cost at the Mohawk is 6.05c. and power and supplies 2.59c. per ton. The notable saving in present practice is in the decreased labor necessary. The old No. 2 Quincy 'rock house' employed 17 men per shift, now only 3 are required. The present working cost for this 'rock house' is stated as averaging less than 2c. per ton, and I am told that when working at full capacity,

CALUMET & HECLA REGRINDING PLANT. NOTE THE CRANE FOR REMOVING MILLS AND MOTORS FOR REPAIRS. THE CONCENTRATING TABLES ARE TO THE RIGHT AND LEFT ON THE FLOOR BELOW.

handling 1000 tons per shift, the cost is not over 1½c. per ton for monthly averages. Comparing this with coarse crushing at the Ray Consolidated mine, Arizona, handling 8400 tons per day, at which the cost per ton during the second quarter of 1914 is reported as 3.337c., it is seen that the advantage lies with the Lake Superior practice. It may justly be argued that these figures are not comparative, since the Lake Superior costs do not include any amount for interest and depreciation, but even allowing for this, the Lake Superior work is apparently the cheaper. Whether better results could have been attained by adopting centralized crushing in the beginning is somewhat beside the mark, since it is clear that the advantage is now problematical and is in any case too small to justify the reconstruction necessary to adopt it at the present time. A step toward the central crushing idea was taken when the Ahmeek No. 1 and No. 2 shafts were equipped. In equipping these shafts the crushing plant was placed nearly midway between the two shafts, which are 1500 ft. apart, and the ore is conveyed to it by semi-automatic tramways. The designer here fell between two stools, failing to secure the advantages of a large crushing plant placed adjacent to the stamp-mill and linking up two shafts to a single crushing plant by means of equipment which is conducive neither to simplicity of operation nor economy of cost, which is reported as 4½c. per ton. We may therefore conclude that, on the whole, there is but little room for improvement in the present best coarse-crushing practice of the district. Considerable change may in time be made, but can scarcely lead to any large decrease in the cost of preliminary crushing.

Concentration

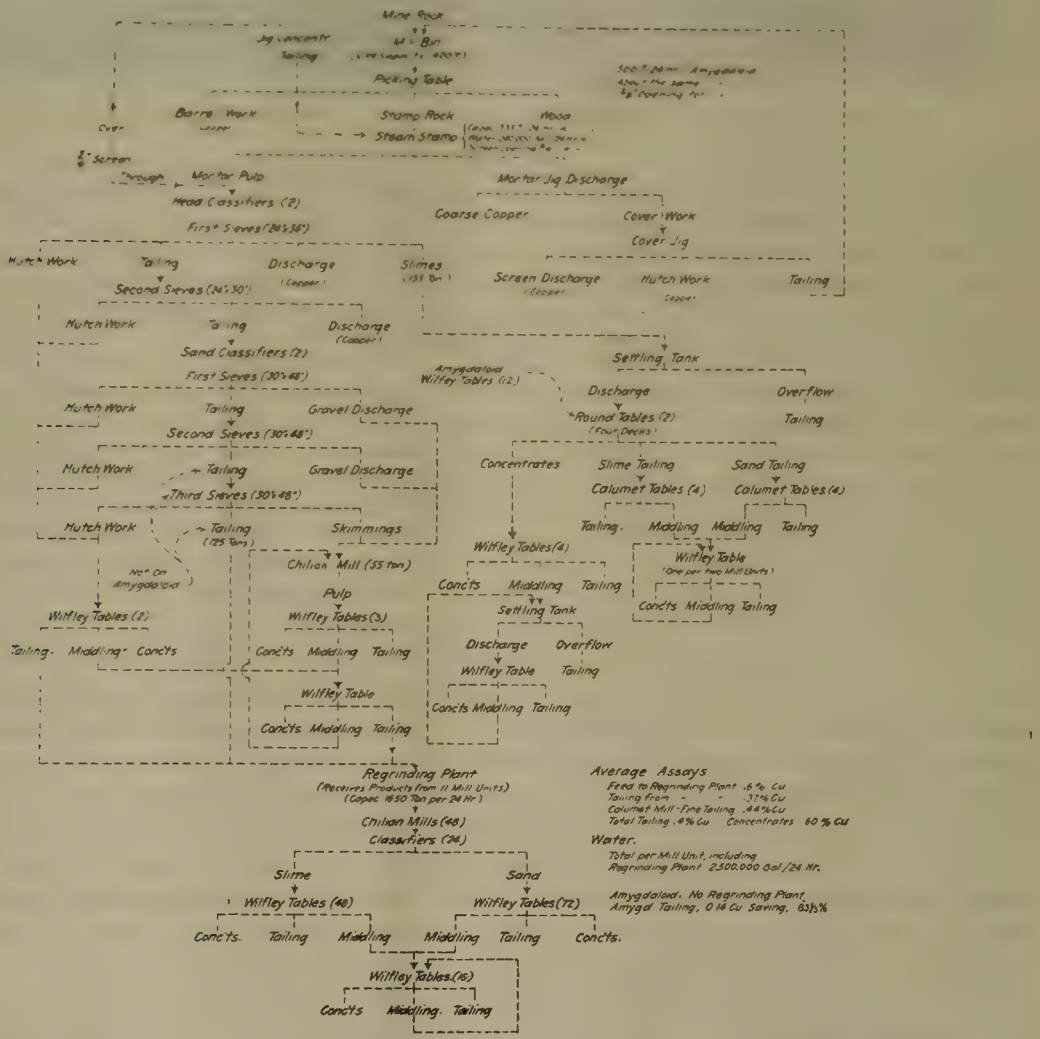
The methods of concentration pursued in the district are the logical and inevitable outcome of the conditions which have to be met; namely, masses of a tough and ductile metal disseminated through rock, and in pieces varying from microscopic size up to masses weighing several tons. The method which must be followed is to free the large masses from adhering rock and separate them out so that suitable means may be taken to recover smaller particles. The large masses are separated out in the 'rock house' and the rock broken away by blows of an air or steam hammer. Particles of copper larger than 4 to 6-in. ring do not find their way to the stamp-mill, therefore, but are diverted to the smelter, and it has already been indicated that the chief end of coarse crushing is the preventing of larger masses of copper from reaching the mills. At the mills the crushed ore, 4 to 6 in. ring and finer, is fed to steam stamps which crush it through $\frac{3}{16}$ to $\frac{5}{8}$-in. mesh screen. Some provision must be made for the masses of copper which are just small enough to pass the feed opening and which cannot possibly be reduced to pass through the screen except by a process of gradual attrition, which not only causes a tremendous consumption of power but also leads to the loss of most of the copper thus ground away. This is provided by an ingenious device known as the Krause discharge, a 5-in. pipe opening into the bottom of the stamp mortar. Through this pipe rises a hydraulic jet sufficiently strong to prevent ore from working its way into the pipe but not strong enough to prevent the heavier copper from so doing. The jet serves to provide part of the battery water needed for crushing; the coarse copper liberated by the blows of the stamp accumulates in the pipe, where it does not interfere with crushing operations, and by opening a gate valve from time to time it is quickly discharged without interrupting crushing operations. This provision for the removal of coarse copper appears like a detail of milling practice; it is in reality a vital factor. From time to time the suggestion is made that gyratory crushers and rolls would prove more economical crushing machines than jaw-crushers and stamps, and they have even been tried, though it would scarcely seem that an experiment would be necessary to demonstrate that a mass of copper, just small enough to pass the feed opening of a gyratory or a set of rolls would at once put the machine out of commission. Any superior mechanical efficiency in regular operations is more than counterbalanced by the frequent delays thus caused. Masses of copper too large to pass the jaw crushers are easily pulled out with a chain block and tackle, while the coarse copper is removed from the stamp, as indicated, without hindering regular crushing operations.

In order to give opportunity for this collection of copper the mortar must be made more roomy than is the custom in stamping gold ore, and this in turn requires the use of an unusually large amount of water in order to secure quick discharge of the crushed material. This necessitates placing the stamp-mills at a point where an abundant supply of water can be cheaply obtained. The early mills were therefore placed along the shores of Portage lake, but when this was made an inland waterway by the dredging of the ship canal to permit exit to Lake Superior at its head the tailing could no longer be discharged into the channel, and the mills were removed to their present positions on Torch lake and elsewhere. The move proved a good one for those that chose Torch lake as their new site, for the tailing since accumulated is now recognized as a considerable asset. Those companies which had to seek sites on the outer edges of the peninsula were not so fortunate, since the winter storms sweep away most of the tailing and often batter away the cribwork through which the water supply is drawn, as has been described by Edward Koepel in the *Transactions* of the Lake Superior Mining Institute for 1912. Another drawback of a millsite on Lake Superior is that it generally involves a greater length of haul for the ore. The small increase of cost due to this factor may easily be more than offset by any one of a number of other factors which will suggest themselves. Transportation as a factor in operating costs, though it represents as much as 14c.* out of a total of $2 per ton for mining and treatment or almost two-thirds of the cost

*At the Calumet & Hecla the cost is 6c.; at Isle Royale 4c. per ton.

of milling, may be dismissed with the statement that it differs little from railroad transportation problems everywhere, and except for the effect of the rather rigorous winter climate of the district on the moist ore in bins and cars, the effect of the rather heavy snowfall on winter traffic, and the influence of relative situations, mentioned above, it has no especial significance.

The operations of concentration are rather simple, as indicated by the accompanying flow-sheet, which is reached. Until very recently every effort was made to recover all the copper freed from the rock by the stamp, but the copper in the crushed particles of ore was allowed to escape unheeded in the tailing. The amount that thus escaped in the earlier milling work was sufficient to render the tailing fair grade ore of today. Through the researches of C. H. Benedict, metallurgist for the Calumet & Hecla, regrinding of the tailing from the concentration of the stamp pulp has been introduced



TYPICAL FLOW-SHEET OF MOST MODERN LAKE SUPERIOR MILLING PRACTICE.

typical of the best practice of the district. It is interesting to remark at this point the analogy with the biological fact that an individual in its development summarizes the history of the development of the race. Something of this sort can be discerned in the operations of concentration, when we remember that the earliest mining in the district was directed toward the securing of large masses of copper, and from time to time efforts have been made to recover smaller and smaller particles until, as indicated farther on, the ultimate limit is and developed to a point in which it is one of the most important of the series of operations.

Referring again to the flow-sheet, it is seen that the principal operations of milling include dewatering and classifying the stamp pulp, concentration of the classified material on Wilfley tables, regrinding the tailing in Hardinge mills, and re-treatment on tables without classification; leaching of the table tailing will eventually be adopted. This general plan has been developed on the results of some decades of experience. It would be

SPARE MILL ON STAND; NOTE CAR INSIDE BUILDING.

METHOD OF DRIVING REGRINDING MILLS.

interesting to trace the historical development of Lake Superior milling practice, but it would take us too far afield here. The introduction of the Woodbury-Benedict jig classifier was an event of importance, as it at once furnished a means of removing some of the floods of water introduced into the mortars, of removing the coarse copper liberated by the stamp, and of furnishing a classified feed for the Wilfley tables. The use of these latter is the standard practice of the district. They are simple, cheap, and efficient, and nearly all the millmen of the district seem to believe that the better saving claimed for other types of tables is not sufficient to compensate for their greater cost. Whether this general opinion is based on experimental results or mere 'information and belief,' I cannot say.

Present practice in regrinding is due to the initiative of C. H. Benedict, who, perceiving that the way to recover copper escaping with the tailing is to recrush so as to set it free, set about determining the most efficient method of performing the work. Chilean mills, Hardinge mills, and a 5 by 18-ft. tube-mill were studied in comparison over a considerable period. The results definitely disqualified the Chilean mills, as might perhaps have been expected, since I have already pointed out that with a tough ductile metal occurring in ordinary rock the means of crushing adopted must imitate the blows of a hammer, breaking away the brittle rock from the tough metal, an action for which grinding machines are but ill adapted. In addition, the cost of repairs is heavy with this type of machine. Both tube-mills and Hardinge mills are well adapted theoretically to the work to be performed, and the result of the work of the Hardinge mill was enough superior to the tube-mill to lead to its adoption. The advocates of tube-mills are inclined to question this, urging that experiments with tube-mills of various sizes and designs would perhaps have given different results. With such a discussion we have here no concern, the vital factor being that a means has been devised for regrinding and reconcentrating the coarse tailing at a cost which permits a profit to be made on the copper recovered by the operations.

The operation of these Hardinge mills is sufficiently unusual to require further discussion. The ground pulp is not classified, as the coarse copper thus liberated would be returned to the mill until it was ground away and lost. The mills are therefore fed with only a small quantity of thin pulp, a 20 in. by 8-ft. mill, driven by a 40-hp. motor handling 35 tons of solid in a 4 to 1 pulp per day. In crushing amygdaloid, this runs up to 55 tons. The ground product all passes 40-mesh and 50% will pass 200-mesh.

I have already referred to the fact that some of the copper occurs in particles of microscopic size, lying along the cleavage planes of the minerals in the ore, that in some of the newer mines much of the copper is thus finely disseminated, as contrasted to the 'mass' ore mined in earlier years, and that in all the mines 'mass' copper tends to be less in evidence with increasing depth. The recovery of this fine copper is therefore not only a problem of present weight, but will be of increasing importance. It is evident that this copper cannot possibly be recovered by any of the ordinary methods of wet concentration. Two methods seem possible; flotation and leaching. It would seem that the leaf-like form in which such copper undoubtedly occurs would render it unusually amenable to flotation, but I am told that some preliminary experiments indicated that this is not the case. Leaching the ore has the advantage that it can be applied directly to the tailing from the tables in the grinding plant, from which it can extract the copper without any further grinding. On the other hand, so far as at present developed, it cannot be applied to the considerable quantity of slime made in the preceding crushing operations, and the tailing from the regrinding plant will doubtless have to be deslimed before subjecting it to leaching. It is quite possible that a combination of leaching for the sand tailing and flotation for the slime will prove more satisfactory than the use of either alone, since flotation cannot recover any except free metal, and the cost of grinding sufficiently fine to liberate the valuable mineral is a large factor in the use of flotation.

The sand recovered by dredging is elevated by a belt-conveyor to the distributer bins at the head of the regrinding plant; the Hardinge mills are set on an elevated platform of steel, so that their discharge may go directly to the tables on the floor below. Each mill is driven, through Wuest gearing, by its own motor and, as seen, a crane travels the full length of the plant and

can pick up either a mill or motor. Spare motors are kept on hand, a broken motor can be replaced in a few minutes, and the defective one repaired at leisure. At the far end of the plant two concrete stands to support mills are provided. On one of these a mill ready for use is always kept; a defective mill is lifted out by the crane, its contents emptied into the waiting mill, and the defective one set aside for repairs. The mill just filled is put in the place of the one removed and work proceeds with a total delay of as little as 25 minutes. Methods of design and operation such as these show their direct results in decreased operating cost and increased output. Standard-gage railroad tracks running into the plant also decrease handling costs.

Ordinary leaching methods could not be used with this ore, as the use of acid solutions or salts of an acid radical is rendered impracticable by the presence of considerable quantities of calcite, which would cause a prohibitive consumption of the chemical reagent. A clever modification of the ordinary cupro-ammonium reaction for the absorption of oxygen has therefore been devised by C. H. Benedict; this method was discussed in more detail in an editorial in the *Mining and Scientific Press* of September 5, 1914. Construction of a 2000-ton leaching plant to employ this process was started early in 1914 and it would doubtless have been in operation by the end of this year if the situation with respect to copper created by the war in Europe had not rendered it necessary to stop all new construction for the time being. It must be made clear that while I have here discussed regrinding of tailing and leaching as features of standard concentration practice in the district, the use of regrinding has only so far made its way into the mills under control of the Calumet & Hecla, Winona, and the Copper Range companies, while the first leaching plant is yet only in process of construction. Regrinding and reconcentration will be adopted by all the mills as soon as their own operating conditions render it practicable, and the same will be true of leaching if it proves as successful as hoped.

The success attained in regrinding and reconcentrating tailing and the indicated success of leaching operations naturally directed attention toward the tailing accumulated from earlier work. Of this the Calumet & Hecla alone has 40,000,000 tons, averaging 16 lb. copper per ton, and it has been computed that the recoverable copper content of this is 560,000,000 lb. It is thus seen that a tailing pile may become a tremendous asset, and the disadvantage of a millsite where the tailing is carried away and lost is thus clearly brought out. In the case of the Calumet & Hecla, Tamarack, and other nearby mills this tailing has accumulated in the quiet waters of Torch lake. A suction dredge, described in detail by the *Mining and Scientific Press* of November 22, 1913, has been built by the Calumet & Hecla to recover this sand and pump it to the regrinding plant on shore, where it will undergo regrinding, reconcentration, and leaching. On sand containing 16 lb. copper per ton it is estimated that 5½ lb. per ton will be recovered on the tables, and 70% in the remaining sand (excluding slime) will be recovered by the leaching operations. The details of the proposed method are given in the editorial, already mentioned.

Summarizing the foregoing, it may be said that recent developments in milling practice have extended rather than transformed time honored methods. Improvements have been made in equipment and design, which increase the efficiency and decrease operating cost, but what is of most significance is the introduction of methods which permit the recovery of the copper which formerly escaped in the tailing. The current tailing from the mills treating Calumet & Hecla conglomerate ore contains 8 lb. copper per ton, and the use of methods which permit this tailing to be reduced to 2 lb. copper per ton is practically equivalent to permitting the treatment of ore containing 6 lb. less copper per ton than was formerly profitable, with a correspondingly great increase in the ore reserves and the probable profitable life of the district. Perhaps even more important is the fact that the new methods recover the finely divided invisible copper which was formerly ignored, but which will have to be considered in future mining operations, and, as already indicated in the preceding, article, it may prove no longer possible to depend upon the eye alone in exploration and stoping. The average cost of stamp-milling is given by five companies as follows:

Cost of Stamping

	Baltic.	Champion.	Mohawk.	Osceola.	Wolverine.
1911..	$0.187	$0.230	$0.219	$0.172	$0.264
1912..	0.214	0.202	0.220	0.181	0.260
*1913..	0.271	0.279	0.295	0.235	0.370

*Strike year.

Smelting

There are four smelting plants in this district; that of the Michigan Smelting Co., owned jointly by the Copper Range, Mohawk, and Wolverine companies and situated 2½ miles west of Houghton, on the south shore of Portage lake; the Quincy Mining Co. smelter, on the north shore of Portage lake, just across from Houghton: the Lake Superior Smelting Co. plant, owned by the Calumet & Hecla, at Dollar Bay; and the new smelting plant of the Calumet & Hecla Mining Co. at Hubbell, which includes an electrolytic refinery that was completed early this year. It must be admitted in the beginning that smelting is the least advanced of the operations of the district. The best work I consider that at the Michigan smelter, which was designed by Frank Klepetko and built by F. I. Cairns in 1903. The copper concentrate is brought from the mills to the smelter in 40-ton cars and is dumped into bins where the 15% or more of moisture which it contains drains away and dries out. Provision for drying it by means of the heat of the waste gases was first made, but this proved unnecessary. All the concentrate, some of it containing as little as 22% copper, is smelted in 35 by 16-ft. reverberatory furnaces. These are fired with soft coal, using Traylor stokers, and smelt 95 tons per day each, or 4 tons of charge for each ton of fuel. The copper is drawn

out of two furnaces and into a third, placed between them and at lower level, in front. Here it is oxidized and poled in the well known way, and is then cast, into the various shapes required, upon a Walker casting machine. The arsenic content of this copper is such as to make it suitable for the rolling of sheets and the drawing of seamless tubing, so that some of it is cast into cakes 5 ft. square and other into enormous wire bars for these uses.

The slag from the reverberatory furnaces, averaging 80-tons per day in amount, is so high in copper (8%) as to require re-treatment. This is run into molds, cooled, and crushed and elevated to the bins above the blast furnace by a link-belt elevator. Here it is mixed with 20% (by weight) of limestone, 6½% coke, and 6½% soft coal. All the coarse or 'mass' copper is charged into the blast-furnace, for a variety of reasons. (1) It makes a good deal of slag, which if made in the reverberatories would have to be resmelted; (2) it gives a large fall of copper, which is necessary to dissolve the metallic iron formed by the strong reducing action of the furnace, which would otherwise accumulate and form a sow; (3) it is cheaper to remelt the copper thus produced than it is to resmelt the slag. The copper drawn off from the blast-furnace is cast into sows weighing about 6000 lb. each. These are lowered by a crane through an opening in the roof of the refining reverberatory which is ordinarily covered by a lid. The slag from the blast-furnace contains 0.9% copper and is run to waste, but has been impounded so that if it is ever found feasible to re-treat it, by leaching or otherwise, it can easily be recovered. The copper from this plant is not further refined, and finds a ready market for the making of hard copper articles, wire for screens, copper sheets for such uses as locomotive fireboxes, and for the making of seamless copper tubes.

Practice at the other smelters is different because most of their material is free enough from arsenic so that it can be sold as Lake copper, which commands a premium for its purity. The coarser copper is purer than the fine, and all the material which is over 60% copper is smelted in reverberatory furnaces, refined in the same furnace, and cast into commercial shapes. The fine concentrate, containing from 60% copper down to 22% copper, is melted down in a reverberatory in order to agglomerate it. The agglomerate, together with the slag from the reverberatory furnaces, is then smelted in a blast-furnace, together with some limestone, yielding a slag which contains about 35% Fe and 31% SiO_2. It is interesting to note here that one of the principal constituents of the fine concentrate is epidote, the green silicate of lime and alumina. The easy basal cleavage of this mineral causes it to form small polyhedra when crushed, and although it has only a specific gravity of 3.4, it tends to come off the tables along with the heavier but leaf-like copper. Recent changes in milling practice result in the saving of more of the magnetite, which is present in the ore, but in a fine state of division, and this is a welcome constituent, as it yields iron to the slag. To the casual observer this method of smelting seems unsatisfactory, since the copper is in large part converted into a silicate by the fusion in the reverberatory, and the subsequent reduction of this silicate in the blast-furnace necessitates the use of 20% of anthracite as fuel, thus producing a degree of heat at which some of the copper must be lost by volatilization since the furnace flame is distinctly green. At one of the smelters the fine concentrate is briquetted, but it would seem as though there should be no difficulty in sintering it, following the practice used elsewhere of handling flue dust.

The copper made by blast-furnace smelting requires refining, and is remelted, cast into anodes, and refined electrolytically. Some of the coarser copper contains enough silver to make it worth while to refine it, and it is therefore smelted separately and sent to the electrolytic refinery. The only electrolytic refinery in the district is the newly built one of the Calumet & Hecla Mining Co. at Hubbell, to which operations have been transferred from the old plant at Black Rock, near Buffalo, New York. This handles so much of the copper of that Company as is high enough in arsenic or silver to need refining, and also treats the same product of the other companies of the district. The plant is an interesting one, and deserves description in detail, but its technical operation has no bearing on our present theme, and therefore cannot be gone into here. The reason for the transfer of the plant from the East to the Lake Superior district is also interesting, but may not at once be obvious. The chief cost of refining is the electric energy required, and by placing the plant near the mills and smelter it gets the benefit of the central electric generating station, while its steady electric load helps to produce a better power factor. In other words, increasing the total electric load decreases the disturbing effect of those departments in which the load is fluctuating. Fuel costs but little more at Lake Linden than at Lake Erie ports, since the ore-carrying boats return up the lake in ballast and are glad to carry cargoes of coal at a low figure, coal on the dock at Lake Linden only costing 30c. more per ton than at Cleveland. The cost for smelting, refining, freight to the East, and marketing, in the case of those companies which report it, averages 20c. per ton of ore milled, ranging from 13c. to 31c. This variation probably indicates that there is room for improvement in the methods pursued in some cases, but I have not sufficient data on this point to speak more definitely, and, as already indicated, the variations in methods of account-keeping make it necessary to use comparative figures of cost with caution. Generalizing from the few companies which report details, it may be said that the cost of coarse crushing ranges from 1½ to 8.6c. per ton; transportation from mine to mill, 3 to 17.5.; stamp-milling, 18.7 to 40c.; smelting, freight on copper, and selling costs, 13.9 to 31c. per ton of ore milled. Progress will consist in the cutting down of costs everywhere to the lower level.

Mineral Resources of Jujuy Province, Argentine Republic

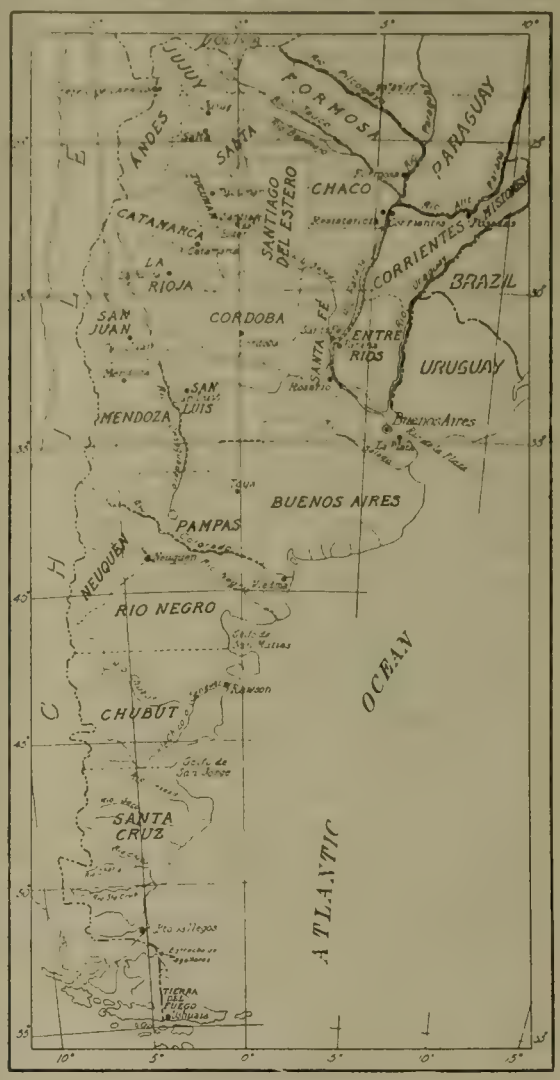
By ARTHUR W. JENKS

This province is situated in the northwestern corner of the Argentine, and is bounded by Bolivia both on the north and on the west. The production of gold from placers has been considerable in the past, and when the government of the province desired me to make a detailed examination of the mineral resources last year, I accepted with pleasure, because the scattered data regarding that region that had reached me had predisposed me in its favor. There would be no utility in giving a detailed description of all the properties visited. It will suffice to say that the principal placers and borate deposits, and all the other important mining districts, were reached, and that abundant samples were taken.

There are innumerable quartz veins, the strike in the majority of cases being north and south, parallel to the slates and shales that form the mountain ranges of most of that region. Almost all the veins are interstratified with the slates; a few strike north and south, but dip differently from the slates. Generally, the quartz is white, with little iron pyrite and with slight stains of oxide of iron. The very rich quartz formerly mined evidently was extracted either from rich veinlets of quartz, very narrow, or from nodules of rich quartz included in the masses of barren vein matter. The distribution of these nodules in the quartz unfortunately has no regularity; that is, a uniform mineralization in the veins of the province does not appear to exist, and the wide quartz veins do not have commercial value, showing only traces of gold. However, I shall mention the mine in Rinconada, called the Veta Blanca, and the mine El Torno, 13 kilometres northeast of Santa Catalina, both of which are worthy of investigation. Due to the fact that the workings are full of water, no positive statement can be made as to the richness of the quartz now exposed in the veins; but considering the large amount of work done, and the unanimous testimony as to the previous richness of the quartz extracted, it would be a legitimate mining risk to unwater those mines, in view of the fact that the quantity of water to be pumped is not likely to be large in either case.

In reference to the placers, these have been very rich, and there is little doubt that much gold still remains in them. None of them is being exploited on a commercial scale at present. In many of the valleys of that region, in the rainy season, when for a short time there is sufficient water, the natives wash the gravel and gain a precarious livelihood. There still remain several areas that are worthy of being explored systematically, despite the fact that in the most of the placers the richest portions have been worked out. Locally it is considered that the presence of these placers, which yielded so much gold, proves the existence of rich quartz veins. This opinion does not take into account the great erosion and consequent concentration of the wide veins of low grade quartz and veinlets of rich quartz which jointly have furnished the material of the placers.

In reference to the placers of the river Orosmayo, it is not my intention to enter into the details of the notorious fiasco of the Orosmayo dredging companies



MAP OF THE PROVINCES OF THE ARGENTINE.

some years ago; but from the gulch of Uriuri opposite the mountain peak Cabalonga northward to the point where the Orosmayo river joins the Granadas, the gravel in the valley is without doubt auriferous. In this distance there are forty kilometres that are worth exploring with the hope of finding a quantity of gold such that a dredge could extract it profitably. Among in-

vestors, no one now would place reliance on the results of the former prospecting work done along the river; besides, the number of prospecting pits sunk was apparently entirely insufficient. From the dredging of 2.5 km. of the river, 140 kg. of gold is said to have been produced. The dredge with which this extraction was effected is still in fair condition, and would need relatively few repairs and no large expense to put it into working condition again. The depth of the dredged gravel was 10 to 15 ft.; dredging stopped at a stratum of hard clay, but the bedrock should be prospected. The boulders encountered were not too large to be handled easily. It probably would be practicable to dig a large number of prospecting pits by hand, but in many cases the amount of water would compel the use of drills. The freight by burro or mule to Abra Pampa, the nearest station of the government railway, is $15 U. S. cy. per metric ton. The distance is 110 km. The cart road to Abra Pampa is partly destroyed by floods, but could be repaired provisionally at small expense, sufficiently to bring any heavy pieces of machinery. But in the plateau region of the province of Jujuy it is cheaper to carry small pieces by burro, mule, or llama than by cart, because the fodder for cart animals is expensive. The dredge formerly employed *yareta*, a resinous moss, for fuel; this *yareta* now is only to be found at some distance from the valley, is not very abundant in any case, and would cost $6 to $8 U. S. cy. per metric ton delivered at the dredge. The railway having been built through Abra Pampa, gasoline or crude petroleum can be brought in tank cars from Buenos Aires, and would form the cheapest fuel at present. In the month of April the quantity of water in the Orosmayo river was found to be 1.5 cu. m. per second. During the rainy season (December, January, and February) the quantity is much greater. Pasture and fodder of all kinds are scarce, and there are rather extended areas where poisonous grass is found that injures or kills mules and horses, especially those that have been raised at a distance and have not become accustomed to this grass. This valley appears to be worthy of a systematic and properly conducted prospecting, in spite of the unsavory failure of the former dredging companies in Orosmayo, which have injured Argentine mining so much. The collapse of the dredging companies of San Juan del Oro, in Bolivia, just north of the Argentine boundary, increased the aversion to mining so strongly felt by Argentine capitalists. The Orosmayo river runs northerly into Bolivia, where it is known as the San Juan river; but there the gravel is very deep, and the gold, if it exists in profitable quantity, is at such a depth that it is likely to remain unmined.

Another placer that may be mentioned is situated 20 km. west of the town of Santa Catalina, and is called La Eureka. It occupies a narrow plateau that forms the divide between the river San Juan and the river Santa Catalina. There are no quartz veins visible, but the deposit is an old channel of the San Juan river, in spite of the great difference in level between the mine and the present stream. Numerous working pits, 30 to 45 m. deep, were made by the miners of long ago, from the surface of the plateau down to the gravel of the old channel. More recently certain Englishmen drove an adit 500 m. from the eastern slope of the ridge to drain the gravel; it passed first through red clay and then entered the conglomerate; unfortunately, the adit was started at too high a level, the ancient bed of the stream remains still flooded with water, and the miners were not able to reach the bedrock, though all accounts agree that the small quantity of gravel they did extract below the level of the adit proved to be rich. It would be necessary to use drills from the surface of the small plateau above in order to prove this ground. In a few places in the adit the conglomerate is copper bearing, the maximum thickness of this ore being 50 cm.; a selected sample yielded 19% copper.

No Lead or Antimony Mines

As to the lead ores of the province of Jujuy, they do not contain gold, and with the exception of certain narrow veins do not assay well in silver. From these considerations, and from the fact that the most of the lead veins are distant from the railway, I consider that at present there is little opportunity for a profitable business in working the galena ores of the province. Farther north, in Bolivia, I visited important lead mines, the ores of which, while low in silver, occurred in sufficient purity and width to be profitable.

Antimony does not occur in commercial quantity in Jujuy, though across the line in southern Bolivia veins of stibnite are found, but were not being exploited when I was in Bolivia, because of the low price of antimony last year.

The double borate of lime and soda occurs in two districts, in Coyaguaima and in the department of Cochinoca. The former is a small deposit, but interesting as showing the probable origin of all the borate deposits of the province. It is an excellent example of the formation of borate from the waters of springs. The water that issues at present is insignificant in quantity, and cold, but the apertures through which the mineralized water formerly issued are very numerous, and the borate and carbonate of lime that have been deposited around them prove the origin of the deposit. The borate is not covered by a layer of earth or sand, but the white silky mineral is either at the very surface or beneath a layer of the carbonate of lime that was also precipitated from the water. The deposit slopes away from the central portion where the apertures are most numerous, becomes thinner, and within 150 m. disappears entirely. A selected sample of borate from it gave the following analysis:

	Per cent.		Per cent.
B_2O_3	39.66	Na_2O	7.59
SO_3	Trace	Total water	37.00
SiO_2	0.70	Loss and undetermined	2.87
CaO	12.18		
MgO	None		100.00

In the locality called Guayatáyoc, in the department

of Cochinoca, the 'Borax Trust' has an important holding in what is really the nearly dry bed of an extensive ancient lake at an altitude of over 11,000 ft. The borate bearing ground at this point is irregular in its boundaries, but is roughly 20 km. long by 1.5 to 7 km. wide. Everywhere in the neighborhood of this property, prospecting pits were sunk 1 m. deep by the 'Borax Trust,' and a few pits were continued to greater depths; but these latter did not show additional strata of borate of commercial importance. Guayatáyoc is 75 km. from Purmamarca, the nearest railway station. The thickness of the stratum of borate varies between 20 and 75 cm., with a probable average of 30 cm. It is found entirely in a continuous layer, not in rounded balls as at Tres Morros farther south. The borate is usually covered by a layer of earth or sand that in places attains a thickness of 50 cm.; but sometimes the borate is found at the very surface.

Methods of Mining Borate

To extract the borate the capping of earth is shoveled off and the tough borate cut with picks, breaking it thus into large pieces which are left in the sun to dry. The borate fields are not worked in the rainy season. It is necessary that the mineral should be well air-dried before it can be cleaned from the adhering sand and earth. The large pieces are broken into smaller ones of about 10 cm. diameter, placed in a screen with 1.5 cm. openings, and shaken rapidly by hand. Thus the earth, sand, and a large amount of borate rubbed off the large pieces pass through the screen, while the cleaned pieces of borate remain in the screen and are ready to sack, weigh, and ship to Purmamarca. The fine that passes the screen is not utilized, despite its high content of borate; probably 25% of the original boracic acid content of the stratum of borate is thus lost. The workmen are paid by contract $2.60 U. S. cy. per metric ton of sacked borate. The burro freight thence to Purmamarca is $12 U. S. cy. per metric ton. The Company makes no effort to exploit these deposits on a large scale; it only aims to do the assessment work required by the Argentine law, and the present production is only incidental to that work. The cost of production in the Company's borate fields in Chile and in Peru is much less than in Jujuy; therefore, it is prudent for them to save the Argentine deposits for future use, when the more cheaply worked deposits shall have been exhausted. The production in 1913 was approximately 750 tons of borate from the Guayatáyoc field. A sample of sun-dried borate gave:

	Per cent.		Per cent.
B_2O_3	31.20	MgO	Trace
SO_3	Trace	Na_2O	12.48
SiO_2	7.70	Total water	30.64
CaO	12.60		

The valley in which the borate and salt deposits of Jujuy are situated is 200 km. long and from 20 to 40 wide, with an altitude of 11,000 to 12,000 ft. The valley forms an interior basin without present outlet, and the evaporation of the ancient lake has caused the extensive deposits of borate and of rock salt. In the dry season it is possible to ride horseback over the larger part of the borate ground, if one knows the safe roads; otherwise the animals may mire in the sticky sand that never becomes entirely dry. The area covered by salt is safe, because the hard surface of this sustains the horses perfectly. In the rainy season, from the end of November to the beginning of March, the salt deposit and the greater portion of the borate field are changed temporarily into a large shallow lake. It is necessary to wait a couple of months each year after the evaporation of this lake before the extraction of the borate can be re-commenced. The working season is about seven months, extraction being impossible the remainder of the year on account of the wetness of the ground.

The principal Argentine office of the Compañía Internacional de Borax, or the 'Borax Trust,' is in Buenos Aires, but the local office is at Tres Morros, department of Tumbaya, province of Jujuy. The area owned by the Company near Tres Morros is more important than that in Guayatáyoc, and the tonnage of borate that has been proved is undoubtedly large. Here, as in Guayatáyoc, the Company does as little as is possible, simply endeavoring to perform the required amount of annual work. The whole valley has been prospected for borate, and it is unlikely that other profitable areas exist, aside from the properties of the 'Trust' and apart from the smaller holdings of two neighboring, independent companies. From Tres Morros to Purmamarca the distance is 60 km., and the burro freight $11 U. S. cy. per metric ton. The borate of Tres Morros is found sometimes at the very surface, and sometimes beneath as much as 30 cm. of earth, and the thickness and quality of the strata of borate vary much. The mineral occurs both in a solid stratum and also in rounded balls; the latter are usually purer than the former, and have apparently been formed by the erosion of the solid strata of borate, the resultant pieces having been rounded and purified by the action of water. The average thickness of the layer of borate at Tres Morros may be given as 25 cm. The methods of extraction are the same as at Guayatáyoc. The sun-dried borate shipped runs from 37 to 38% boracic acid. In air drying, the mineral loses half of its weight. The production in 1913 at Tres Morros was 1800 metric tons.

Roasting to Reduce Weight

The Company has experimented on a limited scale with the roasting of the air-dried borate in order to reduce the freight bill by lessening the weight. The cost of wood fuel is excessive at Tres Morros, being $13 U. S. cy. per metric ton; as 25% of the fuel is used for the motor and for the cylindrical roaster, there is little advantage in roasting in the present plant, despite the fact that between moisture and flue dust escaping, the reduction attained in weight is one-third.

The deposit of rock salt in the province is extensive; it is little worked owing to high transportation costs. The salt beds lie to the west of Tres Morros and extend

in a northeasterly-southwesterly direction for 40 km., with a workable width of from four to seven kilometres. In the central portion, the salt attains a depth of half a metre, and is purer than near the edges, where the salt is at present being cut. But the thick blocks that would result from cutting the salt from the central portions would yield blocks that would not be so convenient for transportation by burros and llamas. The blocks are chopped with axes and weigh from 15 to 17 kg. each. In the rainy season, the salt beds are flooded, and the water attains a maximum depth of 1½ m.; but the depth at any one point varies greatly according to the wind; the temporary lake is so shallow that the water is often forced by the wind to flow from the northeast to the southwest or vice versa, the force of the waves being such as to destroy the monuments that mark the mining claims, unless they are carefully constructed. The extraction of salt in Jujuy in the year 1913 was 1500 metric tons. The freight paid to Purmamarca, the nearest station of the government railway, is $13 U. S. cy. per ton. The following is an analysis of the salt:

	Per cent.		Per cent.
Insoluble	1.12	Magnesia	Trace
Water	1.60	Loss and undetermined.	0.22
Sodium chloride	95.33		
Potassium chloride	1.07		100.00
Calcium sulphate	0.66		

As far as known, the only extensive deposits of profitable mineral in the province of Jujuy are the above mentioned beds of borate and of salt. The working of these on a large scale is impossible under the present conditions of transportation. The construction of a cart road that shall be permanent even in the rainy season would be very expensive, and freights will always remain high even with a cart road, for pasture and hay are scarce at all seasons in the valley that is followed by the road, and always will be scarce because of the lack of cultivable land in the valley. In the winter and early spring, July to October, there is practically no pasture, and the burros make the round trip from Purmamarca to Tres Morros and back with almost nothing to eat. With a cart road it would be necessary to haul much hay to Tres Morros from Purmamarca for the use of the cart mules. An extensive system of wire rope tramways would solve the problem, and a cheaper solution would be a narrow-gage railway northward 110 km. from Tres Morros to Abra Pampa, a station of the government railway. Both solutions of the transportation difficulty are expensive, but would be justified by the tonnage in sight, if the Borax company were well disposed to the project. But, even with the facilities afforded by a narrow-gage railway, it is probable that it could still place borate in the European markets more cheaply from the Peruvian and Chilean properties than from the holdings in the province of Jujuy.

Petroleum has been sought in the northern Argentine at several periods and, it must be admitted, with no commercial results as yet. The localities that show the most favorable indications in the province of Jujuy are the one to the west of the railway station El Quemado, and the other at the side of the small lake of salt water called Laguna de la Brea at the northern extremity of the Santa Barbara range. None of the wells drilled in the provinces of Salta or Jujuy have as yet found oil in profitable quantities. The strata that are oil-bearing form an almost continuous district from Tucumán northward through the Argentine provinces of Salta and Jujuy to Santa Cruz in Bolivia, a town 600 km. north of the Argentine boundary. The geological characteristics of this entire region are closely similar. There are anticlinals that are promising, which have not been explored, or have not been explored properly; and there are numerous seepages of oil. Possibly the seepages in this case indicate that the greater part of the oil has already escaped; but it would seem that up to the present, those who have prospected the oil-bearing area of Jujuy have not taken into sufficient account the geological study necessary before beginning to drill their wells.

Petroleum Probabilities

In my opinion it has not been proved as yet whether the provinces of Jujuy and Salta have oil deposits of commercial importance or not. West of El Quemado a depth of 500 m. was reached, and near the Laguna de la Brea, 705 m. The latter well penetrated hot water with a strong odor of sulphuretted hydrogen; another well put down by the same company obtained a flow of two or three barrels per day. The oil from the seepages of El Quemado is very thick and the quantity is small. The following is an analysis of a sample taken by me:

	Per cent.
Coke and ash	18.31
Hard asphalt	23.35
Oil distilled below 315°C.	50.82
Oil volatile above 315°C.	7.52
Specific gravity	0.9529

The fractional distillation of the oil volatile below 315°C. is as follows:

C.°	Grams.	Density.
Up to 100	2.0 water	
260 to 300	35.5 oil	0.8449
300 to 315	12.7 oil	0.8477

From an abandoned well near the Laguna de la Brea a small amount of thin oil flows, of which a sample was taken that gave the following analysis:

	Per cent.
Coke and ash	8.20
Hard asphalt	9.90
Oil distilled below 300°C.	29.00
Oil distilled above 300°C.	52.90
Specific gravity	0.8777

The fractional distillation of the oil volatile below 300°C. is as follows:

C.°	Grams.	Density.
Up to 100	1.00 water	
220 to 240	8.25 oil	0.7912
240 to 260	5.25 oil	0.8094
260 to 280	7.00 oil	0.8200
280 to 300	7.50 oil	0.8301

But without considering the exact percentage of light oil in the petroleums, it is certain that an abundant de-

posit of oil would have great value in the northern Argentine, and the continuation of prospecting work is justifiable if the corresponding geological data are properly taken into account.

More interesting perhaps than commercially important are the numerous occurrences of mineral waters in the province. The only hot springs that have been utilized are those at Reyes 13 km. northwest of the city of Jujuy. The conveniences for guests are fairly good and the water appears to possess decided curative properties in cases of rheumatism. There are other hot springs in widely scattered localities, and several springs of cold water with strong odor of sulphuretted hydrogen. As the province is so far north of the large cities of the Argentine, the utilization of these springs as the basis of health resorts has not been seriously undertaken as yet; but with the growth of the country these mineral waters will have decided value.

With the exception of the southeastern portion of the province, fuel is scarce in the mining districts. *Yareta* and the brush called *tola* answer fairly well for cooking purposes, but are not abundant; that is, they would not suffice as fuel for a company operating on a large scale. For the operation of such a mining property, I should prefer gasoline or crude petroleum with the appropriate engines for furnishing motive power, in any part of the plateau of the province, despite the cost of transportation from the railway to the mines.

At these high altitudes the provision of drinking water is always important. In traveling, especially in the dry season, it is necessary to have a guide who knows the springs. With a knowledge of the country there is no great difficulty in obtaining the fresh water necessary for personal use and for the saddle mules and pack animals. But in some localities it would be costly to secure water sufficient for the various needs of a mining company operating on a fairly large scale. In this region also there are few cattle, because of the poor pasture. Sheep are numerous, selling at $1.30 to $1.70 U. S. cy. each. Goats are worth a little less, while llamas sell at $7. The meat of the llama is good, and that of the vicuna is still better. Often there is difficulty in buying these animals, for although they are numerous almost everywhere, the owners, for some inexplicable reason are averse to parting with them, and sometimes it is necessary to kill the animal desired and pay for it afterward. Alfalfa or other hay must be freighted in from the railway, or from the San Juan valley in Bolivia. In the winter, pasture is very scarce in the elevated portions of the province; therefore the best season to go there is shortly after the rains, which cease in February or early in March.

Due to the fact that many Bolivians make their sales and purchases in the northern part of Jujuy, the use of Bolivian money in the departments of Rinconada, Santa Catalina, Yavi, and Cochinoca is almost universal, it being difficult to use Argentine money in those departments except at the post-offices and at the railway stations. The peones who freight goods from the railway to the westward are always paid in Bolivian money, and charge at the rate of 12 to 20c. U. S. cy. per ton-kilometre.

The results of my investigations, though not as encouraging as I had hoped when undertaking the work, at least showed that there exist various opportunities for legitimate mining development operations in the province of Jujuy, operations from which one can reasonably hope for success.

Profits and Holdings of Guggenheim Exploration Company

The net income for 1914 was $3,383,622, equal to 16.27% on the outstanding capital stock. At the end of the first quarter the dividend was increased from 12% to 14% per annum, which is the present rate. The surplus shows an increase of $160,660.

Assets at December 31, 1914:

Total	$45,797,300

AUSTRALIAN comment on the metal situation is varied, but the following remarks by *The Bulletin*, Sydney, are of especial interest: "Last month Great Britain imported 20,185 tons of lead, only 1698 tons of which came from Australia. The remainder, 18,487 tons, was from Spain and America, which can dump lead at low freights into the English market. Much has been written about the supremacy of German metal firms in Australia. Now the plain fact is that Great Britain imports most of its copper from the United States, lead from Spain, and spelter from Belgium. That being so, what else can Australia do but sell to the foreigner?"

Twenty-three mines of Bendigo, Victoria, produced 102,649 oz. gold from 272,420 tons of ore in 1914. Dividends totaled £126,879, and assessments £61,842. The total yield of the district was 163,601 oz., a slight decrease.

Revival of the Meadow Lake District, California

By W. PRINCE CATLIN

The first discovery of gold in the Meadow Lake district, Nevada county, California, was made by Harry Hartley in 1863. Other discoveries soon followed, and during 1864 and 1865 a town, named Summit City, of 3000 to 4000 inhabitants, sprang up on the shore of Meadow lake. A stock exchange was established, mining companies were incorporated, mills were built, and a general mining boom was on. It was soon found that the oxidized ores went down but a few feet, and that the gold could not be recovered from the iron sulphide by amalgamation. This coupled with the hard winter of 1865-1866 caused a general exodus which resulted in the almost total desertion of the town and district. Since then the buildings of the old town have either been removed, crushed to the ground by snow, or burned, until at the present time only three remain standing to mark the spot. The mills suffered the same fate. In more recent years, one property and then another has been worked in a desultory manner and without success. Metallurgical difficulties have been held to be the chief cause of failure, but with the improvements in processes for the treatment of sulphide ores containing gold, capital is being attracted here and a new life is beginning to stir.

Most of the properties of the Meadow Lake district lie from four to nine miles northerly from Cisco on the main line of the Southern Pacific railroad, and it is from this point that the larger part of the mining supplies are packed in over trails. The northern part of the district can also be reached by wagon road from Truckee, a distance of 38 miles. Being situated in one of the belts of deepest snow in the United States, operators are required to make extensive preparations for each winter. The elevation ranges from 7000 to 7800 ft. At this altitude the warm rains of the coast are replaced by snow which accumulates from November to April, and 15 ft. is common. A depth of 35 ft. has been recorded.

The topography of the country is precipitous. Bare granitic rocks, with only here and there a patch of soil with trees and underbrush, characterize the landscape. The predominating formation is granodiorite, while large masses of more basic rock, probably a gabbro, exist in the northeastern, and metamorphic rocks in the southern part of the district. The veins run from one formation into the other without any perceptible change in character or value. They are of the 'fissure-replacement' type, and cut the formations almost at right angles. In some instances the diorite along the vein walls is altered to a schist. This metamorphism undoubtedly took place along the fracture prior to vein formation.

There are two vein systems in the district, one having a southeast-northwest strike and the other an east-west; dips varying from 60 to 80° toward the southwest and south, respectively. The veins of both systems are alike in content with the exception that the ores of the east-west veins carry a small percentage of copper and occasionally of lead. These metals have not yet been found in the other series. The veins are numerous, but irregular in width, being really lenticular masses (some of which reach a maximum width of 30 ft.) occurring at intervals along continuous fractures. The more important ore-shoots are usually found at vein intersections.

HIGH-GRADE MINE.

EXCELSIOR CON. MINES CO. BUILDINGS.

The principal vein minerals are quartz, tourmaline, hematite, magnetite, pyrite, marcasite, chalcopyrite, pyrrhotite, and rarely galena and sphalerite.

The old Excelsior group of patented claims, upon which the first discovery of gold was made in the district, and which has produced considerable bullion from the oxide ores near the surface, was bonded to Worcester, Massachusetts, people last spring, and will be worked under the name of the Excelsior Consolidated Mining Co. During the past five months this Company has had a force of men at work erecting camp buildings, placing machinery, constructing a water-power line from Meadow lake to the mine, and getting ready generally for a heavy development campaign. The property is now equipped so that operations can be carried on during the winter months regardless of weather. In the meantime the metallurgical details will be worked out, and a mill will be erected as soon as ore reserves justify. Maurice M. Johnson, representing Samuel Newhouse, recently secured a bond on the High Grade property from the owners, John P. Clark and Harry D. Ramsay. A small force of men will be worked on this property until spring, when, it is understood, machinery will be installed and development on a large scale commenced. Among other promising claims in the district are the Oro Grandes, Cash In Sight, Gray Eagle, Three Johns, and the Freeman.

The development work done in the district has been limited. Although properties have been held and attempts at mining have been made here for over 50 years, it is safe to say that 2000 ft. would cover all the work done on all the claims combined. And this work, done by the early operators in quest of the oxidized or free-milling ores, is of a superficial character. Work was always stopped when sulphide ore was reached. Frequently, trenches from two to six feet deep along the outcrop of a vein were evidently enough to satisfy the owner that he had reached the bottom of the free-milling ore. The deepest shaft in the district is 115 ft. At this depth a good grade of sulphide ore is exposed; this is also true in the deepest workings of other properties in the near vicinity. The district, therefore, is not without inducements for deeper explorations of its lodes.

With the advent of new operators, combined with the growing tendency of the claim-owners to offer more attractive terms to capital, it is to be hoped that the district is entering upon a period of development which will result in proving the worth and merit of the claims to full satisfaction of the owners who have held on so tenaciously all these years, as well as to those who invest their money in them, and that prosperity will spring anew from the ashes and ruins of former efforts.

VALUE of all the gold produced in the United States from 1792 to January 1, 1914, is estimated by the U. S. Geological Survey at $3,549,799,400; the value of the silver at $1,709,517,600.

BANK CLEARINGS in New York in 1914 totaled $83,018,580,015, compared with $94,634,281,984 in 1913.

The Boss Mine, Good Springs, Nevada

By SEELEY W. MUDD

*Both daily and technical press have erroneously stated that I had purchased this property. I have never been in the district, but I can, however, give some facts with regard to the property, based on a statement by an engineer who is familiar with it.

The Boss claim was located about 30 years ago. The property was originally opened as a copper mine, the gold value at that time not being considered of great importance. Some years later an unsuccessful leaching plant was built to treat the copper ores from this and other properties.

The country rock in the immediate vicinity is a thick-bedded limestone, probably of Carboniferous age, dipping approximately south 60° west at an angle of 10 to 20°. A fault zone, having a direction approximately north 30° east, passes through the main workings on the Boss claim. This fault zone is from 20 to 30 ft. wide, and in it the known orebodies of the Boss mine occur. About 600 ft. northwest of the mine workings a large intrusion of quartz monzonite appears. No igneous rocks have been identified in the mine proper.

The orebody of chief interest may be called a pipe, which outcrops at the surface. Its axis dips to the northeast at an angle of from 5 to 10° from the horizontal. Several cross-faults have caused slight lateral and vertical displacements.

Part of the orebody is quartz, which is generally thoroughly disintegrated and of a light gray color. In places the quartz is nearly black, sometimes vesicular and sometimes rather compact, but nowhere does it occur in large unfractured masses. The quartz body is surrounded by an irregular shell composed principally of hard and soft hematite, although limonite is present, especially near the surface. This shell of hematite is from a few inches to 6 or 7 ft. in thickness. The hematite shell, in turn, is enclosed by malachite, usually about 4 in. thick, but varying from a thin seam to 10 or 20 inches.

The black or greenish yellow talcy material accompanying the quartz core is said to be the richest ore, and the gold content is said to be somewhat higher, in ounces, than the combined platinum and palladium contents. The light-gray quartz ore is considered richer than the compact black quartz ore. It is only in this black quartz ore that metallic gold is noted in hand specimens, although the black ore does not horn so well as the ore previously referred to. The hematite varies greatly in its content of precious metals, but gold predominates in value; the silver varies from an ounce or two upward, and the quantity of platinum and palladium is small, usually negligible. The outer shell of

*Remarks to the San Francisco section of the Min. and Met. Soc. of America.

malachite usually carries from 20 to 30% of copper.

At some points near the orebody the limestone is heavily stained and in part replaced by the oxides and carbonates of copper mixed with iron oxides. A little chrysocolla and chalcocite were noted. The hematite shell sends out little streaks or fingers into the surrounding fractured limestone. The limestone is usually rather coarsely crystalline, light colored, and, while broken by the faulting, has not been brecciated. The orebody is very irregular in size, but one point was noted where a cross-section of the quartz included in the hematite showed an area as great as 70 ft. square. Detached lenses of hematite were noted in several of the adits, and, as a general rule, those of larger diameter than 3 ft. contained a core of disintegrated quartz similar to the main ore pipe.

It is claimed that at one point, a mile or more distant, some ore has been discovered in limestone, which contains platinum and palladium. It may be of interest to note that the discovery of platinum and palladium was made by an assayer who was at first puzzled by the fact that his assay buttons were ragged and irregular rather than round and smooth.

H. F. Bain has referred to a European platinum mine where the ore was reported to occur in graywacke. In the literature on the subject, other than that concerning placers, I have been unable to find any reference to an occurrence of platinum except in connection with rocks of igneous origin, usually peridotite or serpentine. The occurrence of these ores in limestone is exceedingly interesting.

Prospecting Dredging Ground at Pato, Colombia

*Where gravel deposits extend several feet below the permanent water-level, as those of the dredging areas of Pato, there is no means commercially available for accurately determining their gold content. Drilling, which under these circumstances is the most accurate, gives only approximate results, which are subject to wide variations owing to the personal variation of method, carelessness in drilling and panning, varying physical properties of the deposit, and to the economic impracticability of drilling holes sufficiently close together. Having driven a tube and pumped the gravel out of it foot by foot to bedrock, and panned the gravel so extracted, and weighed its gold content, it is desirable to know just what proportion of the displaced gravel and gold entered the tube and subsequently the pump, and what proportion was pushed aside by the tube in entering the ground, and how much was pushed out of the tube in pumping. This proportion varies in different parts of the hole, and also in the different holes, more especially where the physical character of the deposit is different. Many other variable quantities common to all types of drills enter into the process, but suffice it to say that one can only assume an average factor or proportion which is reliable to within perhaps 50% of the true average figure on any individual drill-hole.

In the early drilling of the Pato property, a theoretical factor arrived at in an entirely different field was necessarily used.* For this examination, we had the advantage of a dredge in operation and under our own direction, dredged over an area where we had previously drilled 17 holes. Carefully calculating the area and cubic yards represented by each hole, and knowing the actual yardage and gold yield by the dredge, we determined mathematically the factor for the drill-holes which would give the actual value recovered by the dredge. This factor works out at 387 ft. of hole for one cubic yard of gravel removed. This factor or proportion was then used for all of the holes drilled under my supervision on the Pato property.

Six drill-holes were further checked by sinking shafts alongside. In this checking, the dry weight of the gravel from the shaft and drill-holes was compared, and the drill factor for each case was determined on that basis. In those shafts where there were no water difficulties, the factor obtained in this way checked up closely with the factor obtained by dredging. In consequence, the drill results that have been obtained on the Pato ground during this examination are figured more scientifically than is usually possible or considered necessary.

In calculating the present dredging area of Pato, I have used the results of 89 holes drilled under my supervision, 38 drilled under C. H. Munro, six drilled by A. P. Rogers, and one drilled by E. B. Kimball. In estimating the yardage, a circle of uniform size was drawn on the map about each hole, and the area included in the polygon, formed by joining the points of intersection of the circles, was taken as the area corresponding to that hole. That area and the depth and value of that hole were used for determining the cubic yardage and gross value corresponding to the hole. These figures thus obtained separately for each hole were then summed up to obtain the total area, yardage, and value. In this manner, errors of calculating results are not introduced by varying distances between drill-holes of widely different values and depths. The examination showed a total of 22,419,490 cu. yd., worth $7,092,100.

By assay of the gold recovered from the drill-holes it was found that the bullion fineness varied from 848 to 937.

*Abstract of report of W. A. Prichard to Oroville Dredging Co., December 24, 1914.

TRANSACTIONS on the New York Stock Exchange in January totaled 5,028,113 shares and bonds valued at $56,967,500. In December and January of 1914 the business was 1,847,982 shares and $35,327,000 bonds, and 10,012,404 shares and $88,823,600 bonds respectively.

TRANSACTIONS at the New York Assay Office in January amounted to $3,795,795, against $8,957,563 in that month of 1914.

DISCUSSION

Readers of the MINING PRESS *are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.*

The Copper Beds of the Coeur d'Alene

The Editor:

Sir—I have read the article entitled 'The Copper Beds of the Coeur d'Alene,' by George Huston, appearing in the January 23, 1915, issue of the *Mining Press*. It seems to me that certain points of importance in any geological discussion, and especially in a discussion of mining geology, have been grossly ignored in the presentation of the above mentioned article; namely, the correct use of technical terms, and the careful presentation of the data under discussion by the use of maps and drawings. Economic geology is progressing towards an exact science and articles dealing with it should be clearly expressed by careful phrasing and the use of exact terms. A relapse into the limbo of terminology from which geologists are gradually emerging should not escape criticism.

On page 145, first column, fourth line from the bottom, in the above mentioned article, the word *trend* is used, and the reader is told that "* * * the trend may be divided into two divisions according to the *strike* * * *." *Trend* is apparently used as a nickname for the general area occupied by the Granite Peak syncline; there is no statement of to what geologic body the *strike* applies. *Trend* implies direction and a direction can not be divided into two or any other number of parts. A careful study of the map accompanying the article which purports to be 'Map of Syncline Showing Principal Faults and Area of the Revett Formation' yields no enlightenment on the matter. There is no syncline indicated on the map, and the reader may only conjecture whether the dotted area or the white one is meant for the Revett formation.

The use of the word *filled* in the seventh line, second column, page 145 implies that the Revett, St. Regis, and Wallace formations were laid down in a pre-existing trough. As applied to the Granite Peak syncline this, of course, is not true. The syncline was produced by a folding of the beds after their deposition in a shallow basin of wide extent and with possibly a slight eastward dip at this locality.*

Four lines below is the statement that "Side pressure against the limbs has fractured a *plane line* down about the centre of the *trend* * * *." In vain I look on the map for the "centre of the trend"; further, a *line* has but one dimension, length, and a *plane* line is any line in a plane.

In the third sentence of the first paragraph under the heading 'Revett Formation,' page 145, it is stated that "These beds lie in the *first* or top 350 ft. of the formation * * *." The first 350 ft. of a sedimentary formation lie at the base unless the beds have been completely overturned. This is not the position of the Revett formation on the east limb of the Granite Peak syncline, but is the case at certain localities on the west limb.

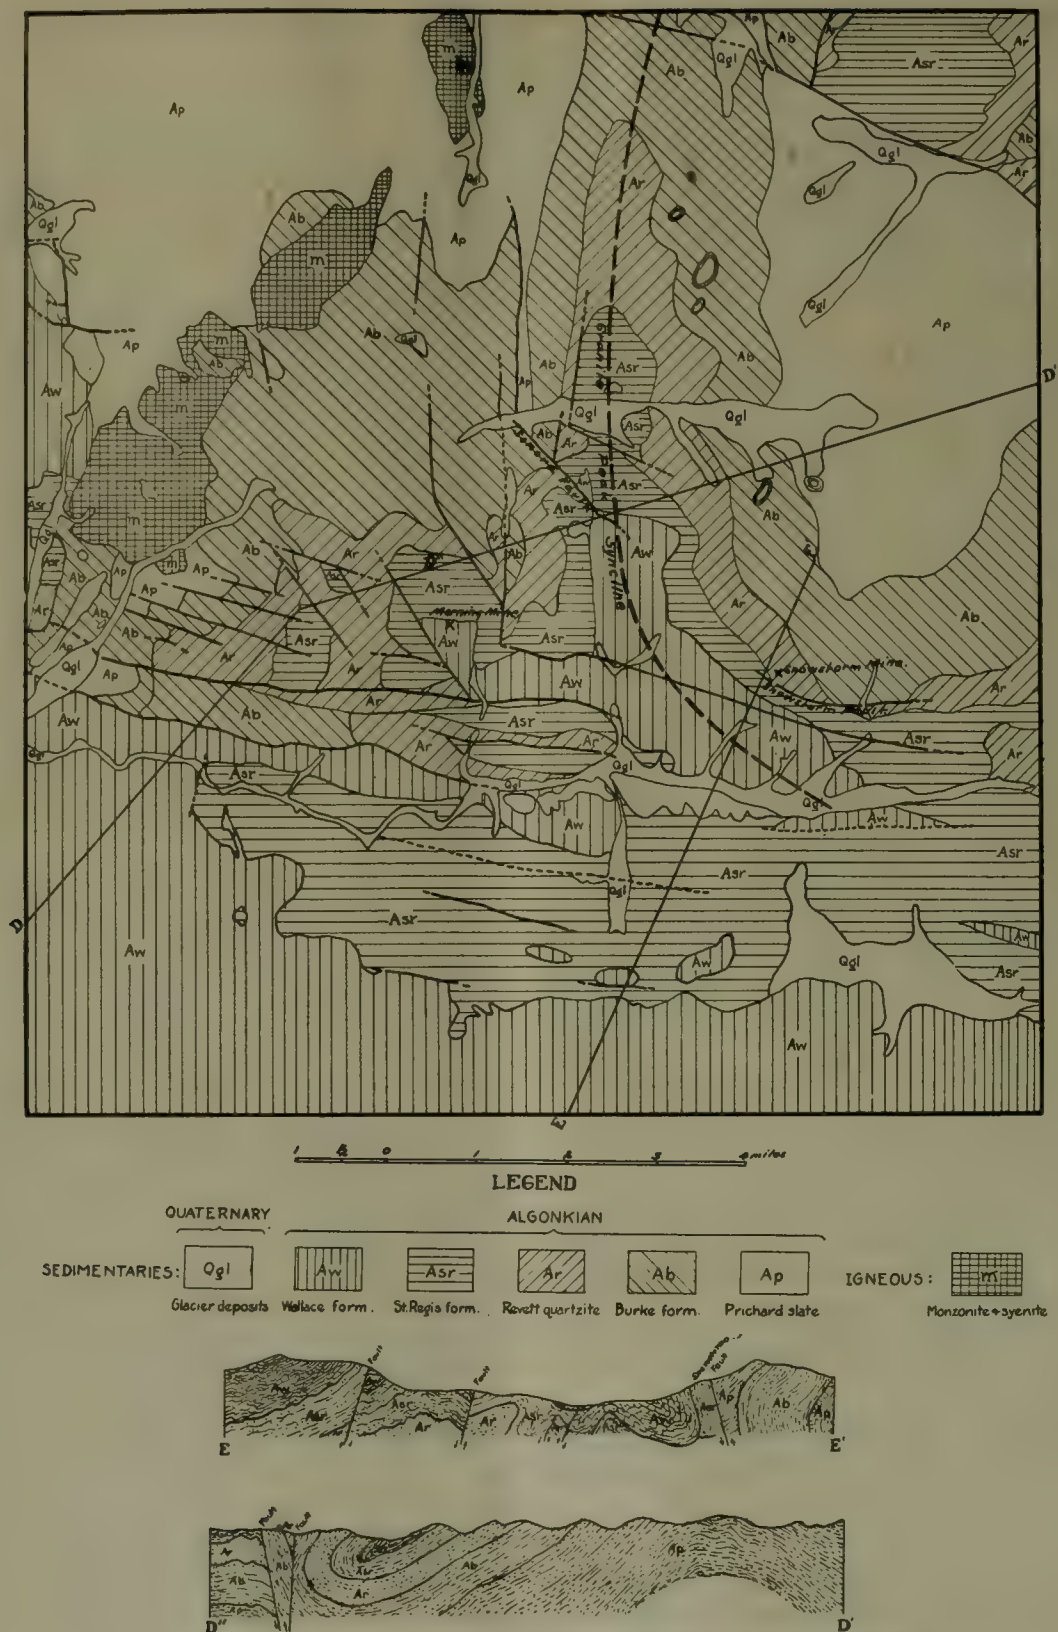
In the second sentence of the following paragraph it is stated that "The faulting, as noted, follows about the centre line of the trough, the Sonora fault on the Canyon Creek slope connecting through with the Snowstorm fault on the Mullan side." I here introduce a copy of a part of the United States Geological Survey map and two sections across the Granite Peak syncline. I have added the heavy dotted line to show the approximate position of the axis of the syncline. A line connecting the Sonora and Snowstorm faults would cut diagonally across this axis or "the centre line of the trough." Neither the syncline, its axis, nor a line connecting the two faults under discussion are shown on the author's map, yet he states that he has studied this small area for seven years.

The succeeding paragraphs are equally vague and misleading. Under the heading, 'Copper Impregnation,' page 146, we see "The deposits are unique in that the nearest igneous rocks are miles away, and there are none whatever in the syncline." A glance at the geological map shows the monzonitic intrusions of the Coeur d'Alene district to be exposed within seven miles of the Snowstorm mine. In the U. S. Geological Survey *Bulletin* 540, page 175, the statement is made that igneous dikes have been cut in the workings of the Morning mine and near-by prospects. The Morning mine is less than four miles distant from the Snowstorm mine and some of the igneous dikes are considered offshoots of the monzonitic masses mentioned above.

The author's discussion of the processes of mineralization suggests a lack of understanding of the metamorphism to which the Algonkian sediments were subjected before the introduction of the metallic sulphides. A complete discussion of this subject is found in *Professional Paper* 62 of the U. S. Geological Survey, and *Bulletin* 540. Under the heading, 'Enrichment Evidence,' is said "Enrichment in this case may be defined as a change in minerals, resulting in a higher copper content *with the casting aside of others.*" It is hard to understand how this escaped the editorial blue pencil.

A. F. Rogers of Stanford University has kindly lent me a specimen of the mineralized quartzite from the Snowstorm mine. This is a typical specimen of the low-grade ore described by Calkins in *Bulletin* 540,

**Prof. Paper* 62, U. S. Geol. Survey, p. 74.



GEOLOGICAL MAP OF GRANITE PEAK SYNCLINE AND MONZONITE INTRUSIVES (IN PART).

(After Ransome and Calkins, U. S. Geol. Surv., *Prof. Paper* 62, Pl. 2.)

U. S. Geological Survey, page 204. The rock is a clean light grayish quartzite impregnated with copper minerals showing no evidence of oxidation. Some time ago Rogers discovered that the dark gray copper mineral heretofore called chalcocite is in reality tetrahedrite.

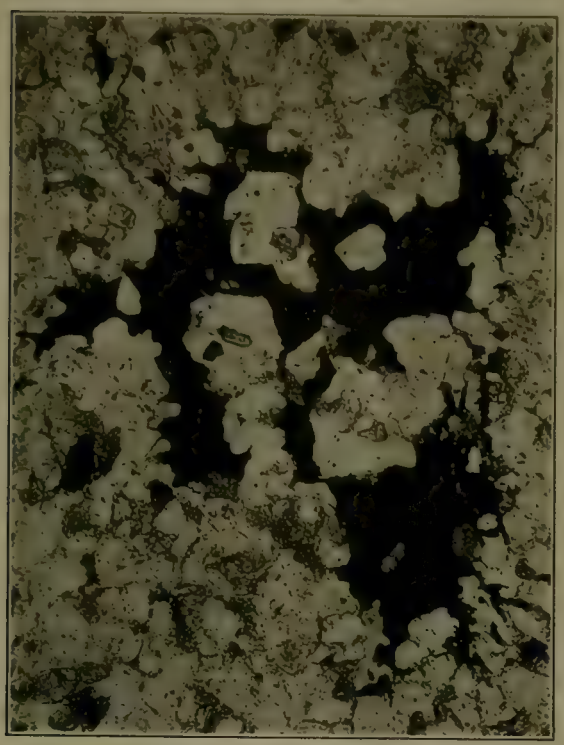


FIG. 1. SPECIMEN FROM SNOWSTORM MINE, MULLAN, IDAHO. BLACK AREAS, PRINCIPALLY TETRAHEDRITE; WHITE AREAS, QUARTZ AND MICROCLINE PLAGIOCLASE; GRAY, FINELY FELTED AREAS SERICITE; × 44 DIAM.; TRANSMITTED LIGHT.

Fig. 1 is a microphotograph of a thin section from the above mentioned specimen. There is no 'silicious' cement proper surrounding the grains of quartz, microcline, and plagioclase. Secondary enlargement of the quartz grains of the original sandstone is visible in places (not shown in the photograph). Sericite is often developed along the contacts of the enlarged grains and also partly, and in places completely, replacing the grains. There is little doubt that this phase of the alteration is the result of metamorphism which altered the sandstone to a quartzite over large areas long before the copper mineralization took place. There is also little evidence of the existence of interstitial spaces at the time of the introduction of the copper-bearing solutions. F. L. Ransome has shown that these solutions were introduced through tiny fractures in the quartzite from which they replaced the sericite and grains of quartz, microcline, and plagioclase. The replacement of sericite and the grains of the quartzite is clearly shown in Fig. 1. The dark areas in Fig. 1 are principally tetrahedrite with a little bornite and chalcopyrite, the white areas are principally quartz with a few grains of microcline and plagioclase. The grayish, finely felted areas are sericite.

Fig. 2 is a microphotograph of a polished section from the above mentioned specimen. The enlargement is 100 diameters and shows the border of one of the larger areas of the copper minerals. In this photograph tetrahedrite is the principal copper mineral, with bornite and

FIG. 2. SPECIMEN FROM SNOWSTORM MINE, MULLAN, IDAHO. T, TETRAHEDRITE; Cp, CHALCOPYRITE; Bo, BORNITE. THE BLACK AREAS ARE QUARTZ AND SERICITE.

chalcopyrite occurring, usually, around the border. There is little evidence of oxidation, the tetrahedrite apparently replacing both the grains of the quartzite and the sericite. Bornite and chalcopyrite usually occur together with the chalcopyrite cutting the bornite. No chalcocite whatever was found in this specimen, but tiny veinlets of covellite were observed, under the high power objective, to be cutting the tetrahedrite and replacing the bornite and chalcopyrite. Covellite occurs only in very minute amounts. It is hard to conceive that this type of ore from the Snowstorm mine is the result of downward secondary enrichment.

JAMES C. RAY.

Palo Alto, California, January 28.

[The Editor must divide blame with the author for the faults criticized by Mr. Ray. The original manuscript was materially condensed before publication, possibly not altogether wisely. Mr. Huston submitted with his article a part of the Geological Survey map of the area involved. Being printed in colors, it could not be directly reproduced, and so a sketch map was prepared indicating especially the position of the faults and the mines discussed by Mr. Huston. It was expected that

this would be used in connection with the original map, to which reference was made on p. 146. While the title was, possibly, a bit indefinite, we cannot believe that anyone was otherwise than wilfully in doubt as to which areas indicated represent the Revett formation. These, however, are minor matters and of relative unimportance. Mr. Huston presented an explanation of the occurrence of copper in the Revett formation, and stated briefly his evidence. Publication of his article has called out from Mr. Ray statement of the evidence for a contrary view, and Mr. Ray has been good enough to prepare a map satisfactory for use with both papers. The whole subject is one of much interest, and we will be glad to hear from others familiar with the field.—EDITOR.]

Electric Smelting in 1914

The Editor:

Sir—Commenting on Mr. Keeney's interesting article on electric smelting in the *Press*, January 2, I am moved to correct an erroneous impression which he has formed from statements made concerning the use of coke as a reducing material at Heroult.

On page 25, at the top of the first column, Mr. Crawford states that coke "if finely ground can be used as a reducing agent with satisfactory results." As a matter of fact, in none of our experiments did we use finely "ground" coke. We did find, however, that to obtain satisfactory electrical efficiency when using coke as a reducing material it was necessary to crush it. The degree of crushing found necessary depended principally on the density and crushing strength of the coke used, and varied, with the different cokes tried, from one inch to three inches maximum size.

Our decision to use half coke and half charcoal in making ferromanganese has no bearing on the subject, as this was done to reduce the volume of slag and hence loss of manganese in the slag.

JOHN CRAWFORD, Jr.

San Francisco, January 15.

The Uwarra Mill

The Editor:

Sir—My attention has been called to Andrew Walz's communication in your issue of December 12. I was inclined to overlook this, but several letters to me on the subject have decided me to reply. I shall not attempt to correct all the errors and misstatements in his communication, but will touch on some of the more glaring ones.

He is absolutely wrong when he says that the pulp storage tank had "no provision made to keep the pulp in suspension." A compressed-air connection was called for in the specifications and was provided by the manufacturers. He says further: "Since the plant was readjusted, the filter discharge has consistently averaged less than 30c. per ton." This must be gratifying to all concerned, because the tailing was averaging less than 30c. and had been for a long time when the plant was turned over to him, although it jumped to $3.10 immediately thereafter.

In speaking of the "overloaded belt-conveyors" he doubtless means the bucket-elevator, because the belt-conveyor had a capacity far in excess of the capacity of the mill. The embarrassment of the bucket-elevator was only temporary, and the change in the trommel screen to relieve it was advised long before he arrived and was mentioned in my article which he quotes.

Mr. Walz finds that his quasi-improvements in the mill result in a saving of 6½ tons of coal per day. Inasmuch as the mill only required 7½ tons before, his figures are certainly wrong unless he is milling 50 tons of ore per day at a total expenditure of one ton of coal. A saving of 6½ tons of coal represents about 70 hp. The mill engine at maximum load showed only 94 indicated horse-power. If 70 hp. was saved, there remains only 24 hp., and the tube-mill alone takes more than that. It would be interesting, since one single steam plant supplies all units, to know how much coal was saved by the new hoist over the little old overloaded worn-out steam-eating hoist which it was replacing when he took over the authority. He may have overlooked the fact, also, that the comparative number of drills and the comparative amount of development done account to a large extent for the steam economy stated.

The complaint that the rolls do not assist the tube-mill in "making slime" overlooks the fact that the rolls were installed *to crush* and the *tube-mill to make slime*. He adds: "I am not prepared to state definitely if stamps would have been better than rolls." Then why mention it? In *The Engineering and Mining Journal*, January 9, 1915, one of their "contributors * * * of national reputation as experts in their specialties" says of this very installation it "is an important step toward the elimination of stamps as primary crushing machines," and continues: "Upon ores of a character suitable to such work it is cheaper, both in installation and operation, to use rolls rather than stamps." Also, I might add as pertinent evidence on this point, that the Alaska Gastineau is now building the largest (20,000 tons per day) gold mill in the world along the most advanced metallurgical and mechanical lines and is installing rolls rather than stamps.

PERCY E. BARBOUR.

Bath, Maine, January 30.

Milling Gold Ores in Cyanide

The Editor:

Sir—Noel Cunningham's statements in your October 17 issue seem so strangely at variance with the facts of the case that perhaps I may be permitted to explain why I quoted figures by which, in Mr. Cunningham's opinion, "no experienced metallurgist should have been misled." In contrast to Mr. Cunningham's statement that "It was specifically stated that the Hollinger was just starting up at the time of writing, and milling data were only vaguely indicative," I would refer to the article itself, in which it is stated: "The mill start-

ed operations in June of this year [. . . *six months before the publication of the article*] and the greater part of the elapsed time has been taken up in systematizing the operation * * * The mill is now running well * * * but the management desires to establish the costs firmly before publishing any data." The recovery of gold was stated to be "thoroughly satisfactory" and extraction figures were given without reservation. I fail to see anything to justify the remark that the latter were only vaguely indicative.

Mr. Cunningham misquotes me in dealing with precipitation ratio. Other things being absolutely identical, the figure is often, doubtless, a factor of grade of ore. In the six instances quoted, the ratio is certainly in proportion; but with regard to one of these, the Esperanza, I have already stated* that "The milling dilution, with Huntington mills, is only 4 to 1, against 10 to 1 in most other [Mexican] mills; and the amount of solution precipitated amounts to only 3 tons per ton of ore, as against two or three times that amount in cases where ordinary stamp-milling is practised." Design of plant is only one of many factors affecting precipitation ratio, which, as I stated, is by no means *invariably* proportional to the grade of the ore being milled.

The feasibility of milling in water and the avoidance of discharge of waste solution other than as residue moisture are almost entirely questions of the efficiency of the dewatering apparatus used. For a leaching product a combination of Caldecott cone and sand table is used on the Rand with excellent results. In other cases drag or screw classifiers may be made to act as efficient dewaterers. By such means it is possible to obtain a low moisture product which even permits of the use of a water wash without increasing the bulk of the solution in circuit.

Similar results may be obtained with slime by a variety of means. I have been able to avoid the necessity for discharging waste solution by the use of an intermittent type of settler which I described in *The Mining Magazine* late in 1911. A system described by C. A. Banks in the *Press* of July 26, 1913, is also applicable; and I look for some such addition to the modern Dorr-type thickener which would bring its dewatering efficiency up to what has been my experience with intermittent machines.

In other cases where rapid cyanide treatment is feasible as a result of efficient amalgamation, the slime pulp may be dewatered in the same presses in which it is subsequently cyanided. Evaporative losses during ordinary slime and sand treatment are by no means insignificant and frequently permit of a water wash being used. In the majority of cases, however, the time may be more advantageously employed by a further solution wash. The use of water can only result in mechanical displacement. The use of barren solution may result in a further recovery of gold in addition to displacing that which has been already dissolved.

On the Rand, where milling in cyanide is usual, and where the discharging of waste solution is prohibited by law, the moisture water in the slime residue carries about 0.005% KCN. The total cost of cyanide used in treatment averages about 9 cents per ton milled.

In a postscript Mr. Cunningham quotes a case where improvements resulted from a change from "stamping in water and amalgamation to stamping in solution *followed by continuous decantation and filtration.*" The italics are mine, but the sentence embraces all the available information as to the precise nature of the change. Excellent results have been obtained elsewhere from continuous decantation, and I feel sure that Mr. Cunningham would be the first to question the judgment of a metallurgist who, upon such uncertain evidence, interpreted the results as conclusive evidence in favor of milling in cyanide, *per se*.

In conclusion, and to prevent misconceptions, I would restate the fact that my arguments with reference to the advantages of milling in water are not meant to apply to silver or silver-gold ores where, on account of low amalgamation efficiency and for other obvious reasons, milling in cyanide has been proved to be the more effective method.

A. W. ALLEN.

**Mining and Scientific Press*, May 14, 1914.

U. S. Geological Survey Exhibit at the Exposition

The central feature of the Survey's exhibit at the Panama-Pacific Exposition, San Francisco, will be two stagelike settings—partly model and partly painted—representing a district in the arid West both before and after development. In the before-development scene, topographic engineers are at work with their instruments on the headlands, geologists have stripped a bed of coal and are taking samples for analysis, and other geologists are studying rock formations. In the foreground is an automatic river gage; farther back a hydrographer is measuring the flow of the stream as it races by. In the background is a camp and pack train.

The second scene shows the same district after development. The results of the stream-gaging have been utilized in planning a power plant that shows in the distance an irrigation project that covers the valley floor. The coal bed is being mined, an oilfield with derricks is under development, a sandstone bed is being quarried, and mining and milling are in progress in the mountains. A town has also sprung up, and roads, railroads, and other evidences of civilization abound.

The scenes are illustrative of the basic work of the Survey and also explain why this organization is not even better known than it is. It carries on the pioneer work and prepares the way for the engineer and the constructor; but when these men appear on the ground to erect permanent monuments to their professions, the Survey disappears from the scene and moves on to new fields.

CONCENTRATES

Readers of the MINING PRESS *are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.*

WIRE ROPE consumption in the Transvaal amounts to nearly $700,000 in value per year.

DREDGE EXCAVATION at Panama in December totaled 1,227,675 cubic yards.

SINKING the North Butte Mining Co.'s Granite Mountain shaft to 3100 ft. from the surface, cutting stations, and driving cross-cuts to connect up mine workings, cost $227,604, or $71.80 per foot. The shaft-house, electric hoist, and other construction will cost $251,540 by the time the plant has been tested and accepted from the manufacturers.

MINING AREAS in many foreign countries are dependent on other capital than their own for their exploitation, yet the laws are not always to the investors' liking. The Colombian government, Central America, both state and national, is making a laudable effort to promote and foster the development of its natural resources by foreign capital. However, a peculiarity in its laws gives almost sovereign power to the municipalities in the matter of local administration and taxation. Much of the good intent of the government is thereby undone through the tendency of each municipality to fatten on the industry that is unfortunate enough to become established within its jurisdiction. According to W. A. Prichard, the Pato property is continually persecuted by the municipality of Zaragoza, by the levy of exorbitant duties both legal and illegal, so that it is necessary to keep a salaried native lawyer on the property, another at Remedios, the head of the district, and another at Medellin, the state capital.

MINERS' LIENS.—According to California law, a miner who has worked for six months for the lessees of a pile of tailing and has not been paid his wages, may, if the lease is assignable, take an assignment from the lessees and work the tailing subject to its provisions, but in such event would be subject to the terms of the lease in the same manner as the original lessee. He should also protect his right to recover wages for past services by filing a miner's lien on the claim and machinery thereon within 30 days after stopping work as an employee of the lessee, and within 90 days after filing the same should commence suit to foreclose said lien. He would acquire no right to the possession and proceeds of the claim under his lien until after judgment of foreclosure and sale of the claim and improvements thereunder to himself. A notice of non-responsibility posted by the lessor, in order to be effective, must be posted conspicuously on the claim within 10 days from the time when he has notice that work is being done on the claim, and recorded in the county recorder's office, and then becomes effective as to all labor performed. If the owner of the claim knowingly permits work to go on for six months before posting the notice, it is of no effect whatever as to work already performed, but would probably be valid as to future work. Machinery placed on the claim and owned by the lessee would be subject to the miner's lien for the wages due him during his entire period of employment.

The mining district of Mogollon, New Mexico, has obtained a permanent highway outlet to Silver City and other points by means of a novel aerial ferry which was recently constructed across the Gila river at Gila. This overhead tram is of the wire cable type of construction, and is operated by a small power plant. It is 90 miles from Mogollon to Silver City, and at certain periods of the year, before the aerial ferry was built, the line of communication was frequently interrupted for days by floods in the Gila river, which made fording of that stream impossible. It occurred to Thomas Lyons, who owns a farm near the treacherous crossing, that it would be a feasible plan to build a cableway across the river, by which means mine motor-trucks and other vehicles could cross at all times. The platform which is suspended from the cables easily transports loads of as much as 16,000 lb. across the stream. The establishment of this crossing is of great benefit to the mining industry of the Mogollon district.

AERIAL FERRY FOR THE MOGOLLON DISTRICT, NEW MEXICO. BOTTOM PICTURE SHOWS TAKING ON A LOAD, AND TOP ONE CROSSING THE GILA RIVER.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

BOSTON

Lake Superior Coppers.—Convertible Mining Bonds.—Butte & Superior Dividends.—Nevada Douglas Affairs.—O'Reilly Company.—Calumet & Corbin.—Colorado Minerals Separation Company.

Recovery of the Lake Superior coppers on the Stock Exchange and Curb is easily the leading feature of the Boston mining-share market. At present the Stanton stocks, Mohawk and Wolverine, occupy the strongest position. Wolverine interests claim the mine has a life of 15 to 20 years, or about 150,000,000 lb. of copper, making the Company worth about $6,000,000, or $100 per share. In August 1911 J. R. Finlay stated that Wolverine then had but nine years of life, of which 3½ years of this have already passed away. Calumet & Hecla, which has also been played up or down as a played-out mine, has been accumulating stamp-mill sand for the past 60 years which it will take a period of 30 years to treat. Tamarack has accumulated likewise 12,000,000 tons which will occupy it 30 or 40 years. Metallurgy is giving a new lease of life to Calumet and Tamarack, as well as other Lake producers. The stories of the death or depletion of these old mines are turning out to be very much exaggerated.

The strength of Alaska Gold Mines Co.'s 6% convertible debenture bonds, selling around $115, has directed attention to the excellent records made by the convertible bonds of the porphyry group likewise floated by the banking house of Hayden, Stone & Co. Nevada Consolidated, Ray Consolidated, Chino, and Utah Copper all issued 6% convertible bonds. Nevada bonds cost $106 and sold as high as $300; the first issue of Ray bonds cost $105 and sold up to $200; Chino cost $110 and sold up to $200; Utah cost $110 and sold up to $220. Among the several achievements of the porphyry coppers should be noted the fact that they have made the convertible mining bond a popular security, combining investment and speculative attractions. Jay Gould made the convertible bond popular originally, a generation or more ago, in the days of his Erie campaign, but it has been left for the low-grade copper and gold mining companies, with their large ore reserves, to popularize that form of investment in the mining world.

Boston is talking about an increased dividend for Butte & Superior, which is now earning its dividend requirement of $3 per year four times over, and has nearly $1,000,000 in the treasury. However, the conservatism which resisted the pressure to increase the Utah Copper dividend a year or so ago, when that Company was earning the $3 annual dividend requirement twice over, may prevail again, as the dominating influences are the same in both companies.

The Nevada-Douglas Consolidated Copper Co., stock assessable, is to succeed the Nevada-Douglas Copper Co., stock, non-assessable. Capitalization is to remain the same, 1,000,000 shares, par $5. A special meeting has been called for March 4 at the Company's offices at Salt Lake City to effect this reorganization, and the official notice intimates that it is either a reorganization or a receivership. There are 888,100 shares of Nevada-Douglas stock outstanding, and holders of this stock will receive new shares *pro rata* on the payment of an assessment of 10c. per share. The assessment is a necessary one, as the Company is in financial stress, but it is announced that with the reorganization the Company is to take over the Moore Mining Co., with debts amounting to $57,000 included, in which is the money due on the bond and lease of the Western Nevada mine in the Yerington district. On the news of reorganization the stock dropped to 35c., its lowest price. The criticism is made here that an assessment of 10c. per share will not suffice for the Company's needs, and that if a dead company is to be revamped, it should be made into a live one. The assessment will yield $88,810, and there are floating debts of the present Company, bond interest payments, and reorganization expenses to be taken care of, in addition to the $57,000 indebtedness of the Moore Mining Co. Besides, the management has not yet completed the new leaching plant, which represents considerable obligated expense. However, by making the stock assessable, the Company will be in position to make fresh levies from time to time as money is needed.

A meeting of the stockholders of the O'Reilly Gold Mining Co. has been called at Phoenix, Arizona, for February 20 to reorganize the Company into the Marie Mining Co., reducing the capitalization from $2,500,000 to $1,500,000. Haverhill, Massachusetts, capitalists are largely interested in this Company, which owns about 51 acres of mining ground on the northern slope of the North Star mountain, 10 miles south of Breckenridge, Colorado. The mine has an adit 763 ft. into the mountain, and the management expects to reach the main Witch Hazel vein in another 300 ft., at a depth of over 1000 ft. from the apex.
